1849.

INTRODUCTION.

THE first indication of the Crustacea which presented itself during the late Voyage of H.M.S. Samarang, occurred on the 10th of June, 1843, as we slowly sailed through the Straits of Sunda, the surface of which being nearly calm, was swarming with myriads of Stomapodons, such as the transparent *Erichthus* and *Alima*, together with several other genera, as *Phronima*, *Nerocila*, and *Sphæroma*. These were swimming apparently in dense masses near the surface, carried bodily on by the current setting through the Straits, and darting about among themselves. The *Nerocila* and *Sphæroma* rapidly revolve in the water and swim in every direction, while *Erichthus*, *Alima*, and *Phronima* propel themselves more steadily onwards by repeated flexion and extension of the abdomen.

While the trawl supplied us with specimens of these, the employment of the dredge furnished us with several forms of Podosomatous spider-like Crustaceans, which occur, however, most frequently and in the greatest number among coral barriers surrounding islands, where they are found concealed among the coral branches and in the holes of madrepores. I have also taken them from tubular sponges and even from among the spines of the larger Echinoderms. We found them in large numbers in the Mindoro Sea, in twenty fathoms water and sandy bottom, on which occasion they were found entangled in huge bunches of a species of pinnatiferous keratophyte. Mr. Adam White, in the Proceedings of the Zoological Society, has described two new species of the genus Nymphon obtained in this manner, under the names of Nymphon Johnstonianum and Nymphon Phasma.\(^1\) These Crustaceans are very slow and languid in their progression, moving their slender articulations but feebly. In the Straits, we likewise obtained by the dredge several fine specimens of the

beautifully marked Galathea elegans, a figure of which we have given; it is very active in its movements, darting backwards by sudden powerful jerks, snapping its fore-legs quickly together and producing a clicking noise; when at rest the fore-legs are extended in the same line as the body, perfectly straight; when swimming, the tail is first bent under the body and again forcibly reflexed backwards. Near the same spot a specimen of our very rare Tlos muriger was dredged at a depth of ten fathoms, with other species of Crustaceans, chiefly belonging to the genus Philyra and Leucosia. The Tlos, like Oreophorus and Leucosia, is apathetic and inert, slow in its progressive movements, and relying for security upon its stone-like form. Arrived among the islands of the China Sea, crustaceous animals were observed in all their prolific variety, for in these organisms, as in others, the existence of a high temperature seems to increase their numerical importance, and invest them with more singular modifications of form and with greater brilliancy of colour.

Two of the most remarkable Crustaceans to be met with among the group of islands next visited, namely, that of the Meïa-co-shimah, are the Scopinera globosa of De Haan, and the Mycteris deflexifrons of the same naturalist. The former burrows in the muddy banks and sandflats, just above low-water mark, perforating the surface in every direction. In some parts of Koo-kien-san (one of this group) they are so numerous as to impart a peculiar eolour to the shores, when seen at a distance. They walk but slowly and are very inactive in their habits; when disturbed they make awkward scrambling habits to get out of sight, by burying themselves in the mud in the manner of certain Macrophthalmi. The latter genus (Mycteris), although somewhat resembling the genus Ocypode in many particulars, yet differs considerably in regard to vivacity and locomotion; like their swift-footed consimilars, they form superficial burrows in the sandy mudflats, into which they retreat in the same clumsy scrambling manner as do the Scopimeræ on the approach of danger. In some parts of the Mcïa-co-shimahs I have ridden over many acres of sandy mud covered with these bright blue erabs, and on looking behind could perceive a dark straight line made by the passage of the horse, as he caused them to conceal themselves in the soil in his progress onwards. They delight to bask at the mouth of their apertures in the sun, just after the receding tide has left the flats partially dry, and appear then to be most on the alert in procuring food. Here likewise we met with a species of Gelasimus allied to G. Chloropthalmus of Professor Milne Edwards, with bright orange fore-legs, the left one being bigger than its carapace or, indeed, than the entire body, which inhabits burrows, formed obliquely among

the grass in muddy places near the sea. The Ocypode ceratophthalma and other species are collected by the poorer classes as food; they dig them out of their deep sandy burrows with great eagerness and diligence, by means simply of their hands. I have seen the natives sometimes drive them out by insinuating a long pliant twig into the aperture, and have known them also pour water into the hole and so force its occupant to appear; by minutely examining the foot-prints near the burrow, they are able to say with certainty whether it is vacated or occupied by an Ocypode. On the flat sandy beaches of this group, if the stones which the tide has left dry are turned over, hundreds of Porcellanæ are perceived shuffling along, with their bodies closely applied to the under surface of the stones, seeking protection by quickly gliding to the opposite side. Our species, P. pulchripes, is active and bustling in its habits, but another new species (P. versimana), found among the coral-reefs of Koo-kien-san, is apathetic and indolent, and the P. obesula, A. and W., which was dredged from twenty-four fathoms in the Sooloo Sea, was very sluggish in its movements. The Elamena unguiformis of De Haan was found here also; slow in its movements, it lurks concealed in holes of the under surface of stones below high-water mark. A species of Calappa, allied to C. spinosissima, is found in the shallow bays, which covers itself with sand, and when captured feigns death, folding the fore-legs close against the front and retracting the hind-legs under the carapace. All the species of Calappa that I have seen alive are timid and slow-moving. A species of Alpheus, probably new, inhabits pools under stones on the sandy beaches, and when disturbed makes a loud clicking noise by snapping together the claws of the fore-legs; and in the padi-fields, a Gcearcinus, allied to G. lateralis, is very common, running about in all directions, feeding on the larvæ of Libellulidæ and other insects.

The Paguridæ, or Pirate-Crabs, are very numerous throughout the shores of the Indian Islands, taking refuge, some in the prostrate bodies of decayed trees that usually lie upon the strand, some among the loose stones and in the dead leaves and underwood, and some even penetrating the verge of the forest and ascending the trees that border upon the sea. These are almost entirely terrestrial; some, however, are quite littoral in their habits, while others again live at great depths. We obtained one species of Pagurus off the Cape of Good Hope, living in 230 fathoms water, which was remarkable for having fabricated a dwelling in the form of a univalve turbinated shell out of the dead Ancillariæ which abound there, and which are covered with masses of alcyonoid sponge. In the Bashee Group, numerous fine

specimens of the large Birgus latro were obtained. Respecting this species, which lives high up among the mountains, the natives of Batan (one of the islands of this group) tell very remarkable stories, maintaining that it utters a sharp cry when caught, that it bites most severely and defends itself with desperation, that it carries its eyes in its tail, runs with surprising celerity backwards, feigning death when alarmed, and does much mischief in the eoeoa-nut plantations by eutting down the young trees with its powerful forc-legs. From my own observation I may safely affirm that it runs swiftly backwards, feigns death when disturbed, feeds on fruits, and is of immense strength. They are esteemed, especially the femalc in spawn, great delicacies in these islands, and from experience I can say that the partiality for them seems well bestowed. We found the same species at the Meia-co-shimah Group of Islands, where they inhabit holes in the banks among the pine woods, and frequent the cemeteries, where they feed on the bodies of the dead, several being caught in the aet by one of our officers. We obtained several live specimens, as large as a common Lobster, also from the Cocos or Keeling Islands, where they are said to be very destructive to the young cocoa-nut trees, and where their principal food eonsists of the pulp of the coeoa-nut, which they obtain through a round hole made by tearing away the fibres and breaking through the shell. On the flat, weedy, sandy beach of the island of Ibugos (another island of the Bashee Group) I observed a species of Callianassa, which digs pits in the sand in which it coneeals itself until its prey is in the vicinity, when it seizes upon it and drags it below the surface.

In many parts these islands are over-run with various kinds of Sesarma, the species of which differ very much in their habits. Among those I detected as belonging to the fauna of this group, one was found under stones, on sandy flats just below high-water mark; another inhabited the coral recfs; a third, fresh-water rivulets and pools, hiding under stones and logs, and climbing the roots of trees with great facility. Another species, allied to S. affinis of De Haan, has the same habits, but running more about upon the dry land among the roots of grass, &c. One, of a marbled light sandy colour, with pale grey blotches, lives in holes in the sand; another, with a hairy earapace, dark brown and purple, inhabits holes in the sandy beach above high-water mark; while in Mindanao I found a species living in fresh-water rivulets among weeds, and in the forests of Celebes, another under damp stones and logs, at some considerable distance from any water. On the summits of the hills near the sea coast, particularly on those of Koo-kien-san, I procured numerous Talitri and Gammari, from among the roots of the long damp grass in the society of Tropidinoti and

other orthopterous insects, and on one occasion observed the natives employing the *Eriocheir Japonieus*, De Haan, as food, throwing them alive upon the embers of their fire, and, when burnt crisp, consuming them, shell and all.

In the course of our dredgings in the China Sea, numerous new species of Leucosiæ were collected, generally affecting a sandy bottom, and living among the corallines and madrepores at considerable depths. They are seldom found in muddy places, but prefer deep sandy banks, where they move in a sluggish manner, and seem destitute of acute perceptions. Sufficiently protected by their hard porcellanous shells, they want the rapid progression and threatening attitudes assumed by many other genera. We have figured one of the most beautiful of these new discoveries, which is of a dead white colour covered with numerous round crimson spots. The genus Dorippe is another form very common in the China Sea, living in deep water, from twenty to thirty fathoms, on a muddy bottom. The Chinese fishermen often bring them up in their nets, and among large numbers which I have observed in their boats, I have found nearly every individual with an adventitious body (I believe an alcyonoid sponge) attached to the upper surface of the carapace, and retained in its position by the hooked claws of the two small posterior dorsal pairs of legs. This body is divisible into a thin brown layer, with concentric fibres, and an external white lamina with radiating fibres and a dark central nucleus. I have frequently noticed the same peculiarity in Dromia verrueosipes, and in many specimens both of Dorippe and Dromia which I examined in this condition, the carapaces were perfectly soft, as if this foreign body served them as a protection during the period of their moulting. The Caphyrea peetinieola, White, which was dredged by us in the Sunda Straits from thirteen fathoms, bears a small pecten shell in a similar manner, hooking itself on to the ears of the shell by the claws of its hinder legs, its soft carapace being thus secured from harm by this adventitious covering. Sir E. Belcher informs me that he discovered another species in the Gulf of Papagaya inhabiting the single valve of a Terebratula, which he states was in a partially softened condition. Many other genera, as Hyas, Maia, Arctopsis, Mithrax, and Perieera, are known to have similar propensities, loading their backs with foreign bodies, such as sponges, algæ, and other phytozooic and vegetable productions.

Near Manado, in the island of Celebes, I visited a woody tract which harboured numbers of *Gelasimi* of several species, many of them of the most beautifully varied markings and colour. Among them were varieties of our *G. bellator*, of a green colour with black

markings; another was black, with two bright ultramarine spots in the middle of the earapace; while another species was grey, marbled with white, with an enormous light yellow chela. These Gelasimi cover the ground by thousands, stalking about in a deliberate manner, and holding up and occasionally snapping the claws of their huge fore-legs. Notwithstanding that they appear to be over-burdened with this unwieldy member, they are by no means easy to capture, but run quickly to the mouths of their burrows, where they remain stationary, holding up their fore-claws as organs of defence, and, if further pursued, retreat backwards into their holes, their bodies protected by the same member. In the pools of fresh water and under damp stones, a dark olive-green Sesarma with bright yellow blotches was obtained, and on the coast numbers of the elegant and agile Thelphusa grapsoides, which is found on the coral flats left dry by the receding tide. The Chasmagnathus convexus of De Haan is another crab which appears to be rather common among the Philippine Islands. I have found it in the company of Xenophthalmus pinnotherides, in the firm black mud of Manila Bay, where it forms oblique cylindrical holes.

Near the Dyak village of Samahrtan, not far from the mouth of the Lundu River in Borneo, there are certain mud-banks left dry at low-water, and which are perfectly cribriform with the cylindric holes of *Gelasimi*, *Ocypode*, and other genera. When their communities are no longer flooded by the water, these Crustaceans make their appearance in large numbers, but retreat on the slightest alarm into their subterranean burrows. They are of every variety of colour, some of them being milk-white, some purple, others reddish and mottled, while many are perfectly black. So numerous are these crabs, that seen at a little distance they give the surface a variegated appearance, nearly obscuring the original colour of the mud.

In many parts of Borneo, as soon as the water recedes from the shore on the ebbing of the tide, and the large firm mud-flats are left exposed, numbers of Crustaceans of different genera and species issue from their various holes and hiding-places. The males of many species, after looking cautiously around them, stalk a few paces with their huge fore-legs raised, the claws of which they snap frequently together, producing a slight clicking sound, then rushing eagerly towards the females they embrace them with their fore-legs. The salute is very brief, and is immediately followed by the swift retreat of the females into their different burrows. Other species are seen feeding on worms and shell-fish, feeding alternately first with one hand and then with the other. The common species of *Grapsus varius* is

found running over the rocks near the sca, feeding on the Blennies and *Periophthalmi* that quit the water occasionally; they feed also on the different Cirripedes. There is one species (*G. latifrons*, White) that I have found inhabiting fresh-water rivulets and ponds, which, however, has all the quick and wary habits of the other species, and when pursued hides under weeds and stones. Among numerous other forms observed along the Bornean coast, I may allude to the *Sicyonia* of Edwards, which swims in a slow and deliberate manner forwards, and occasionally propels itself backwards with a sudden jerk; it keeps at a considerable distance from the shore, and appears to love deep still water.

The Spheromæ are generally obtained in company with Cymodoceæ, Cypridinæ, Amphipodeæ, and others, among dense masses of floating sea-weeds, where they appear to lead an active predatory life amid the populous mazes of the Sargassum, &c. They are constantly spinning and darting about, rolling up their bodies into a ball, then straightening them, and erawling among the algæ and keratophytes, with a great deal of vivacity. Among the collection brought home in the Samarang, are several species not before known to Crustaceologists. Like the genera Thenus and Ibacus, the Scyllarus lives at some distance from the shore, and in tolerably deep water. It swims in the manner of Crangon, by rapid inflexions of the abdomen, oceasionally springing through the water with the greatest velocity in a backward direction, and, when eaught, wounds the hands with its tail, throwing it about with violent jerks. At Unsang in Borneo, which was the next place visited, I discovered a new species of Alope, (White,) an active restless Crustaccan, darting and whirling forwards and backwards, and frequently producing a loud elicking noise by snapping the elaws of their fore-legs, in the manner of Callianassa and Squilla. Specimens were found under nearly every stone which I turned on the beach at low water. The Gonodactyli appear to differ slightly from the Squillæ in their habits, inasmuch as they are generally found in deeper water, whereas the Squillæ affect the shallow, weedy, and sandy bottoms, within coral-reefs and on flat beaches, where they hide in holes of the banks of pools, across which they dart occasionally in straight lines, leaving a turbid track behind them. Both genera have, however, the same power of producing a loud elicking noise with the elaws of their fore-legs, and of inflicting very severc wounds with their chelæ, using them in a scythe-like manner, like the Mantis which they resemble. The Trapezia are tolerably lively in their habits, with the same manner of hiding and shuffling under stones as the Porcellane, but unlike them they inhabit the coral branches and madrepores of deep sunken reefs.

Many species of *Idotea* and *Iara* would appear to inhabit the sea-weed along the shores, as well as that found floating on the high seas. At the island of Quelpart, I found a large and singular species in considerable numbers in the former situation, and in the Sea of Celebes I met with several new forms among algæ far from land. Off Tampassook in Borneo, to which island we again returned, several Ixa were obtained by the dredge, one of which (our I. megaspis) was new to science; they inhabit very deep water, and are inactive and fceble. Near the same part of the coast several specimens of Parthenope, which simulated death when taken, and species of Lambrus and Arcania, which have similar habits, likewise were obtained from a rocky bottom by means of the dredge. Off Balambangan, our new genus Ceratocarcinus was procured from twelve fathoms water; and at Unsang, on the east coast, another new genus, our Cosmonotus, was dredged among the clear sandy pools within the reef-barrier, which extends along a part of the coast; and near the mouth of the Pantai River a third new genus, our Zebrida, rewarded our research, the habits of which Crustaceans are alluded to in the following pages. On the return of the Samarang across the Atlantic, at which we have now arrived, Erichthi and Alimæ, with their spiny carapaees and elongated abdomens, were obtained, by trawling, in large numbers, swimming in an erratic manner on the surface when the water was ealm. Among the vast quantities of Acalephæ which became entangled in the trawls, were several containing living Phronimæ, which, on being extricated, swam freely about. Here also was obtained, at the same time as Nemichthys of Richardson, our new genus Rhabdosoma, which swims by suddenly straightening its body when in a bent position, moving either backwards or forwards; it is sluggish in its movements compared with other Hyperiadæ. The Phyllosomata, diaphanous and sluggish of movement, were frequently assembled during this calm by many thousands on the surface of the Atlantic, and, together with numbers of anomalous Zoea, afforded ample amusement during the protracted passage. Among the Entomostraeous Crustaeea, several specimens of Cypridinæ of large size (C. Adamsii, Baird 2) were obtained, as they were revolving and darting about the surface. The specimens described and figured in the following pages are deposited in the British Museum. A. A.

¹ Vide Fishes, Pl. X. Fig. 1.

² Ann. and Mag. Nat. Hist., 2nd Ser., vol. i. p. 21.

1. GONATONOTUS PENTAGONUS, Adams & White. (Tab. VI. Fig. 7.)

Thorace supra confertim verrucoso, verrucis depressis; robustâ carinâ dorsali, ab uno laterali angulo ad alterum pertinente, duobus tuberculis in medio.

Fronte medio sulcatà, medio dorsi duabus longitudinalibus impressionibus; ultimo articulo abdominis in femina verrucoso. Primo pedum pari verrucoso, digitis sulcatis.

HAB. Oram Brunensem.

Gonatonotus pentagonus, Adams and White, Proc. Zool. Soc.

Carapace above closely verrucose, the warts depressed; a rather strong ridge across the back, extending from one lateral angle to the other, with two tubercles in the middle; the front grooved down the middle; the centre of the back with two longitudinal impressions; terminal joint of abdomen, in the female, verrucose.

HAB. Coast of Borneo.

When alive, this species is of a brick-red colour, with the chelæ crimson, and the under surface rufous.

4. CERATOCARCINUS, Adams & White.

Thorax subpentagonalis; latera supra insertionem chelarum in magnam spinam paululum prorsum directam producta.

Frons lata et prominens, cornibus conicis inter se valde distantibus utrinque eminens; oculi parvuli, pedunculis brevibus, sulcis in lateribus rostri aptatis. Exteriores antennæ permagnæ, terminales appendices certe dimidià longitudine antennarum, et ultra cornua rostri prominentes.

Chelæ valde elongatæ; latera fere parallela, carpus subpyriformis, sine spinis in parte interiore; acies digitorum convenientes et serratæ. Secundum par pedum longius et gracilius quam postrema tria paria; articulus tarsalis gracilis et elongatus; quartum et quintum æqualia longitudine; quintum par, ut in Eumedono, tam alte positum ut quarti paris insertionem fere celet; tarsales articuli horum pedum crassi; unguis ad extremitatem translucidus.

Abdomen maris ut in Eumedono: femina incognita.

HAB. Maria Orientalia.

Carapace somewhat pentagonal; the sides, over the insertion of the first pair of legs, produced into a large spine directed slightly forwards.

Front wide and prominent, projecting on each side in the form of conical horns, widely separate from each other. Eyes rather small, peduncles short, the eye fitting into a groove on the side of the front; outer antennæ considerably developed, the terminal appendages at least half the length of the whole antennæ, and projecting beyond the horns of the front.

First pair of legs much elongated, the sides nearly parallel, the wrist somewhat pear-shaped, without spines on the inside, the edges of the pincers meeting and serrated. Second pair of legs longer and more slender than the last three pairs; the tarsal joint slender and elongated; fourth and fifth pairs of legs of equal length; the fifth pair, as in Eumedonus, placed so high as nearly to conceal the insertion of the fourth pair; the tarsal joints of these legs thick; the claw at the end translucent.

Abdomen of male, as in Eumedonus; that of female unknown.

This genus is closely allied to *Eumedonus* of Professor Milne Edwards (Crust. vol. i. p. 349), and, like it, comes from the Eastern Seas.

1. CERATOCARCINUS LONGIMANUS, Adams & White. (Tab. VI. Fig. 6.)

Duobus acuminatis transversis tuberculis, ad extremitatem pilis eristatis, in dorso thoracis, post oculos; primo pedum pari minutis verrucis obsito compluribus altis longitudinalibus sulcis; digitis basi exceptâ nigro-fuseis.

HAB. Oram Brunensem (Balambangan).

Cerotocarcinus longimanus, Proc. Zool. Soc.

Two pointed transverse tubercles, tufted with hair at the end, on the back of the carapace, behind the eyes; the first pair of legs covered with minute warts and with several deep longitudinal grooves; the pincers blackish brown, except at the base.

HAB. North coast of Borneo (Balambangan).

When alive, the colour of this species is blood-red, with five light bands across the carapace.

5. PARTHENOPE, Fabricius.

1. PARTHENOPE CALAPPOIDES, Adams & White. (Tab. V. Fig. 5.)

Thorace subtrigono postice truncato, antice rotundato, dorso verrucosiformibus subdepressis tubereulis obsito; lateribus in parte anteriore obtuso rotundato lobo; alto sinu post lobum; branchialibus
regionibus permagnis, compluribus tuberculis, jugo majorum tuberculorum ad angulos latero-posteriores
pertinentium et brevibus æquis intervallis eireum margines alte incisis. Medianâ regione serie magnorum
rotundatorum tuberculorum, anterioribus tuberculis proxime appropinquantibus, posterioribus distantibus;
duabus caveis inter laterales et medianas regiones, et post eaveas duabus altis foveis.

Fronte latâ, obtusâ, antiee rotundatâ, ad extremitatem subemarginatâ, denticulis in lateribus, tuberculiferâ in dorso.

Chelis breviusculis et crassis; brachio verrucoso, validà anteriore spiniferà cristà; carpo externe lævi, serie tuberculorum in superficie interiore; manu serie magnorum tuberculorum pertinentium a digito superiore intus ad basin articuli, exteriore carinà lævi et sine spinis; digitis magnis et validis, inferiore tribus magnis dentibus.

Abdomine in feminâ septem articulis, depressis tuberculis obsito.

HAB. Maria Orientalia.

Carapace subtrigonal, truncate behind, rounded in front, upper surface covered with wart-like, rather depressed tubercles; sides at the forepart with an obtuse rounded lobe, behind which is a deep notch; branchial regions very much developed, covered with tubercles, with a ridge of larger tubercles extending to the latero-posterior angles, and deeply incised at short regular intervals round the edges; the middle region with a row of large rounded tubercles, the anterior of which are close together, and the posterior isolated; two hollows between the lateral and middle regions, and two deep pits behind the hollows.

CRUSTACEA. 35

Front wide, obtuse, rounded anteriorly, slightly emarginate at the end, faintly dentated on the sides, and tuberculiferous on the upper surface.

Fore-legs rather short and stout; third joint verrucose, with a strong anterior spiniferous crest; fourth joint smooth externally, with a row of tubercles on the inner surface; fifth joint with a row of large tubercles, extending from the upper claw to the base of the joint, on the inner surface, outer keel smooth and without spines; claws large and strong, the lower one with three large teeth.

Abdomen, in the female, seven jointed, and covered with flattened tubereles.

Hab. Eastern Seas.

2. PARTHENOPE TARPEIUS, Adams & White. (Tab. VII. Fig. 2.)

Thorace subtrigono, compluribus lævibus depressis rotundatis tuberculis, in regionibus medianâ et laterali majoribus obsito: lobo rotundato integro, in margine latero-anteriore; alto sinu lobum a lateralibus regionibus dividente; lateralibus regionibus dilatatis, rotundatis, postice angustatis, magnis superficialibus crenationibus circum margines; posteriore margine serie validorum obtusorum subconicalium tuberculorum extrorsum et retrorsum directis.

Fronte latâ obtusâ rotundatâ subcrenulatâ, altc sulcatâ, vix lævi in supcriore supcrficie.

Chelis validis tuberculiferis, brachiis uno magno et compluribus minoribus tuberculis in acie anteriore; carpo lævi, externe noduloso; manu subtuberculifero latere in interiore superficie; pedibus posterioribus depressis, marginatis depressis subtriangularibus obtusioribus processibus.

Abdomine in feminâ septem-articulato, obsito tuberculis, fimbriato crebris setis.

Ilab. Maria Orientalia.

Carapace subtrigonal, covered with numerous smooth, depressed tubercles, larger in the middle and lateral regions; a rounded entire lobe on the latero-anterior margin, and a deep noteh, which separates it from the lateral regions, which are dilated, rounded, narrowed posteriorly, with large superficial crenations round the edges; the hind margin with a row of strong, obtuse, sub-conic tubercles, directed outwards and backwards.

Front wide, obtuse, rounded, subcrenulate, deeply channelled, and nearly smooth on the upper surface.

Fore-legs strong, tuberculiferous; third joint with one large and several smaller tubereles on the front edge; fourth joint smooth, externally nodulous; fifth joint with a rather faint tuberculiferous ridge on the inner surface; hind-legs flattened, edged with flattened, subtriangular, bluntish processes.

Abdomen, in the female, seven-jointed, covered with tubercles, fringed with close-set setæ. HAB. Eastern Seas (Caramatta Passage).

LAMBRUS, Leach.

[Additional Species.]

11. LAMBRUS HOPLONOTUS, Adams & White. (Tab. VII. Fig. 3.)

Thorace subpentagono, antice acuminato, ad latera subangulato, postice lato, obsito rotundis æquis tuberculis, majoribus et crebrioribus in regionibus medianâ et branchiali; lateribus crenatis antice, armatis

in medio crassis obtusis tuberculiformibus processibus, postice desinentibus in longâ prominente acuminatâ spinâ extrorsum et paululum retrorsum directâ; acie posteriore octo validis spinis instructâ, marginibus thoracis, cum tuberculis et spinis, fimbriatis longis rigidis subcurvatis setis.

Fronte acuminate triangulari, aciebus subcrenulatis et validà spinà supra canthum.

Chelis ter thorace longioribus; brachiis serie crebrorum æquorum tuberculorum antice; quatuor vel quinque magnis rotundatis tuberculis, paululum inter se distantibus in latere exteriore, quinque validis spinosis processibus a margine posteriore retrorsum et extrorsum tendentibus; carpo serie tuberculorum supra, et tribus validis spinis externe; manu cristâ octo validarum spinarum supra, serie tuberculorum interne, et serie fere duodecim crassarum obtusarum spinarum in acie inferiore.

Pedibus posterioribus gracilibus minoribus, duobus posterioribus paribus longis subcurvatis setis fimbriatis.

Abdomine (in mare) quinquarticulato, crebris setis circum margines.

HAB. Maria Orientalia.

Carapace subtriangular, anteriorly acuminate, somewhat angulated at the sides, wide behind, covered with rounded equal-sized tubercles, larger in the middle and branchial regions, the sides anteriorly crenated, armed in the middle with thick, obtuse, tuberculiform processes, and ending posteriorly in a long, prominent, acuminated spine, directed outwards and a little backwards; posterior edge with eight strong spines and tubercles, the spines fringed with long, rigid, slightly curved hairs.

Front acuminately triangular, the edges subcrenulated, and with a strong spine above the orbit.

Fore-legs three times longer than the carapace, the third joint with a row of equal-sized tubercles anteriorly; four or five large rounded tubercles slightly separated from each other on the outer surface; five strong spiny processes, extending backwards and outwards from the hinder margin; the third joint with a row of tubercles above and three strong spines externally; the fifth joint with a crest of strong spines above, a row of tubercles internally, and a row of about twelve thick, obtuse spines on the lower sharp edge.

Hind-legs slender, rather small, the two posterior fringed with long slightly curved setæ. *Abdomen* (in the male) five-jointed, the crenated margins beset with short hairs.

HAB. Eastern Seas.

IV. CANCERIDÆ.

In their habits, the Canceridæ are evasive and prone to concealment, passive in defence, and though voracious and predatory, they do not exhibit the same activity, intelligence, and cunning as the Ocypodidæ, the Gonoplacidæ, or the Grapsidæ. The Œthræ inhabit deep water, living in sandy mud, among shells and coral débris, while such genera as Carpilius, Atergatis, Xantho, and Chlorodius, select shallow waters along the shores, preferring weedy and rocky bottoms, where they hide among the stones, and prey on shrimps and small fishes. Pilumnus and Trapezia are tolerably lively in their movements; the latter genus having the

CRUSTACEA. 37

same habit of hiding and shuffling under stones as *Porcellana*, but unlike that genus it inhabits the coral branches of deep sunken reefs and the eavities of madrepores.

At the island of Koo-kien-san a species of *Eriphia* was common, hiding under stones below high-water mark, having the earapace, legs, and chelæ covered with stiff red hairs, the colour of the shell itself being dark greenish brown, the legs lighter and banded with dark brown, while the under surface of the body was ultramarine blue, and the terminal joint of the abdomen the same colour.

The Zozymus lives among rocks, hiding in holes, while *Pilumnus* is sluggish in its movements, hiding in the ereviees and eavities of the under surface of stones below highwater mark.

1. CARPILIUS, Leach.

1. CARPILIUS CINCTIMANUS, White. (Tab. VII. Fig. 4.)

Thorace sine dente laterali, latissimo; lateribus in quatuor lobos divisis; digitis nigris, subalbis ad extremitatem; manu in medio latâ nigrâ fasciâ cum nigro digiti immobilis commixtâ; thorace et pedibus lævibus, intense rubris.

HAB. Insulas Philippinas.

Carapace without lateral tooth; very wide; the side divided into four lobes; elaws of fore-legs black, whitish at the tip; fifth joint of fore-legs with a broad black band in the middle which runs into the black of the immovable elaw.

Carapace and legs smooth, of a rich red eolour.

HAB. Philippine Islands.

2. CARPILIUS SIGNATUS, Adams & White. (Tab. X. Fig. 1.)

Thorace valde convexo, supra punctis carinisque latiusculis impresso, aurantiaco, signaturis pallidecitrinis variegato.

HAB. In littore Mauritiano.

Carapace very convex, the upper surface distinctly punctulated and beautifully marked, in the dried specimen, with symmetrical figures of a pale yellow on an orange ground, which are well expressed in our figure; the several regions are separated from each other by shallow grooves, rendering them much more prominent than in other species of the genus; the anterior convex margin is furnished with long crenulations, the erenulation in front being longer than the one behind.

Front slightly projecting, deeply notehed in the middle line with an obtuse tubercle before, and a smaller one behind the eyes.

Fore-legs large, with the claws very black, the under claw with four obtuse tubercles, the hind-legs as in C. corallinus, but the fifth pair are unfortunately wanting.

HAB. Isle of France.

2. ATERGATIS, De Haan.

1. ATERGATIS SINUATIFRONS, Adams & White.

Thorace marginali membro integerrimo, crassiore, omnino subfusco-rubro colore.

Fronte tribus lobis, unoquoque in medio nictato; digitis chelarum cristis pilorum, nigris, summâ extremitate albâ.

Thorace quatuor digitorum latitudine.

HAB. Mauritium.

Carapace with the marginal limb very entire, rather thick, and of a uniform brownish red. Front with three lobes, each notched in the middle; claws of fore-legs with tufts of hair; claws of a black colour, with the extreme tip white.

Width of carapace four inches.

HAB. Mauritius.

2. ATERGATIS SUBDIVISUS, Adams & White. (Tab. VIII. Fig. 3.)

Thorace membro marginali quatuor lobis valde indistinctis diviso; majore parte summi thoracis intense rubrâ, postice subrubrâ; digitis nigris, basi digitorum mobilium flavâ.

Fronte thoracis duobus rectis lobis, proxime oculum sinuatâ.

Thorace trium digitorum octo lincarum latitudine.

HAB. Insulas Philippinas.

Carapace with the marginal limb divided into four very indistinct lobes; the greater part of upper surface of carapace deep red with yellowish spots, behind paler. Claws of fore-legs black, base of movable one yellow; front of carapace with two rather straight lobes, sinuated close to the eye.

Width of carapace three inches, eight lines.

HAB. Philippine Islands.

This species comes near A. marginatus.

3. ATERGATIS INSULARIS, Adams & White. (Tab. VIII. Fig. 2.)

Thorace anterioribus lateribus acic incisore; parte thoracis post hanc punctatâ; reliquâ superiore superficie fere levi, tribus vel quatuor lineis impressis antice.

Manibus rugosis præscrtim supra; digitis et mobilibus et fixis profunde sulcatis. Flaveolo rubro, pedibus colore intensiore; digitis chelarum pallidis; cornu colorato.

HAB. Insulas Philippinas.

Latero-anterior sides of carapace with a cutting edge; part of carapace behind this punctate, the rest of upper surface very nearly smooth, with three or four impressed lines in front; fifth joint of fore-legs rugose, especially above; claws, both movable and fixed, deeply channelled. Pale yellowish-red; legs darker; claws of fore-legs pale horn-colour.

HAB. Philippine Islands. Cuming.

CRUSTACEA. 39

4. ATERGATIS LATERALIS, Adams & White. (Tab. VIII. Fig. 1.)

Thorace lævi irregulari, lineis impressis, lateribus latero-anterioribus in tres dentes latos divisis. Fronte latâ, denticulatâ, in medio subemarginatâ.

HAB. Maria Orientalia.

Carapace smooth, irregular, with numerous impressed lines; latero-anterior margins divided into three broad teeth.

Front wide, denticulated, subemarginate in the middle; fifth joint of fore-legs rugose, elaws tipped with dark brown.

HAB. Eastern Seas.

3. ACTÆA, De Haan.

1. ACTÆA NODULOSA, Adams & White. (Tab. VIII. Fig. 4.)

Thorace et pedibus supra dense obsitis rotundatis tuberculis maximis in chelis et anterioribus marginibus; tuberculo in cantho inferiore; thorace in medio longitudinaliter impresso; acie posteriore rectâ et duabus lincis transversis parvorum tuberculorum instructâ. Chelis et superiore et inferiore carinis longitudinalibus; cornu colorato.

HAB. Mauritium.

Carapace and legs, above, thickly covered with rounded tubercles, largest on fore-legs and fore-margins of carapace; a tubercle on the under orbit; carapace, in the middle, longitudinally impressed; the posterior edge straight and furnished with two transverse lines of small tubercles; elaws, both upper and under, with longitudinal keels, and horn coloured.

HAB. Mauritius.

4. XANTHO, Leach.

1. XANTHO DEPRESSA, Adams & White.

Thorace valde depresso, antice tuberculato, compluribus tuberculorum acuminatis.

Fronte in medio profunde nictatâ; lateribus tribus dentibus. Manibus extra tuberculatis, tribus posterioribus articulis pedum parvis tuberculis, paucis capillis.

HAB. Insulas Philippinas.

Carapace much depressed; in front tuberculated, many of the tubercles sharp-pointed.

Front deeply notehed in the middle; sides with three teeth; fifth joint of fore-legs tuberculated on the outside; the three last joints of legs slightly tuberculated, and with a few hairs.

HAB. Philippine Islands.

2. XANTHO CULTRIMANUS, Adams & White.

Thorace supra convexiore; fronte nictatâ; lateribus quatuor dentibus; parte anteriore et lateribus parvulis tuberculis; thorace post oculos impressis lineis quæ in medio conveniunt; manibus quatuor longitudinalibus impressis lineis in superficie exteriore quæ parvis subasperis tuberculis exornatur; thorace et pedibus flaveolis rubro commixtis.

Hab. Insulas Philippinas.

Carapace slightly convex above, front notched, sides with four teeth; front part and sides with very slight tubercles; carapace, behind the eyes, with impressed lines, which meet in the middle; fifth joint of fore-legs with four longitudinal impressed lines on the outside, which is covered with small roughish tubercles; carapace and legs pale yellowish varied with red.

HAB. Philippine Islands. Cuming.

3. XANTHO LAMELLIGERA, Adams & White.

Thorace supra convexiore, quatuor dentibus in utroque laterc; superiore parte ad latera subsuberculari. Manibus extra asperis; acie carpi superiore margine dentato; acie manuum et supra et infra margine lamellari; pedibus posterioribus in acie superiore lamellaribus.

HAB. Mauritium.

Carapace rather convex above, with four teeth on each side, upper part on the sides slightly tubercular, fifth joint of fore-legs rough on the outside, edge of fourth joint, above, with a toothed margin; edge of fifth joint, both above and below, with a lamellar border; hind-legs, on the upper part, lamellar.

HAB. Mauritius.

5. CHLORODIUS, Edwards.

1. CHLORODIUS HIRTIPES, Adams & White. (Tab. XI. Fig. 4.)

Thorace levi.

Fronte latissimâ, vix in medio nictatâ; lateribus quatuor dentibus obtusis.

Chelis longis, brachio crassissimo; acie superiore ad basin uno crasso dente; pedibus posterioribus multis fuscis capillis.

HAB. Insulas Philippinas.

Carapace smooth.

Front very broad, searcely notehed in the middle; the sides with four blunt teeth.

Fore-legs long; fourth joint very thick, upper edge, at the base, with one thick tooth; hind-legs with many brownish hairs.

HAB. Philippine Islands.

2. CHLORODIUS FRAGIFER, Adams & White. (Tab. XI. Fig. 2.)

Thorace obsito tuberculis rotundatis bacciformibus gregatim dispositis, definitis impressis lineis separatis; pediculo oculi duabus spinis prope oculum dispositis; pedibus tuberculis oryziformibus obsitis, albis, latâ carmineâ longitudinali lineâ per medium in fronte; quinque carmineis notis in posteriore thoracis parte.

HAB. Insulas Philippinas.

Carapace covered with roundish berry-like tubercles, arranged in groups and scparated by definite impressed lines; pedicel of eye with two spines close to the eye; legs covered with rice-like tubercles; white, with a broad pinkish longitudinal line down the middle in front; five pink marks on hind part of carapace.

HAB. Philippine Islands.

3. CHLORODIUS PILUMNOIDES, Adams & White. (Tab. IX. Fig. 3.)

Thorace et pedibus fuscis pilis obsitis; thorace depressiore; lateribus tribus dentibus, spinis exornatis, priore parte thoracis compluribus eminentiis et spinosis tuberculis asperâ. Manibus magnis; acie superiore serratâ extra et supra tuberculis majoribus; digitis extra et supra sulcatis compluribus tuberculis ad basin digiti mobilis; digitis nigris; concavis extremitatibus albis; pedibus posterioribus supra serratis.

HAB. Singhapuram et Insulas Philippinas.

Carapace and legs covered with brown hair; carapace somewhat depressed; sides with three teeth covered with spines; fore part of carapace with several bosses, and rough with spiny tubercles; four transverse raised lines on hind part; the inmost the shortest; fifth joint of fore-legs large, upper edge serrated on the outside and top with rather large tubercles. Claws on the outside and top channelled; several tubercles at the base of the movable claw: claws black, the hollowed ends white; hind-legs serrated above; second and third joints with three rows of serratures.

HAB. Singapore. Philippine Islands.

4. CHLORODIUS AREOLATUS, Milne Edwards. (Tab. XI. Fig. 3.)

Thorace tuberculis et granulis multis obsitis.

Fronte latâ, iu lobos quatuor distinctos iucisâ; margine latero-anteriori in quatuor dentes triangulares diviso, hiatu anguli canthi interno angusto.

Chelis granulosis, pedibus posterioribus sublævibus.

Abdomen (feminæ) articulis septem.

HAB. Insulas Philippinas.

Chlorodius areolatus, Milne Edwards, Crust. vol. i. p. 400.

Carapace covered with tubercles and granules.

Front wide, divided into four distinct lobes; latero-anterior margins short, nearly straight, and divided into four triangular teeth; fissure of orbital angle internal, narrow, lodging the movable joint of the outer antennæ.

Fore-legs granular; hind-legs and lower surface of body nearly smooth.

Abdomen (of female) seven-jointed, fringed with setæ.

HAB. Philippine Islands.

6. PANOPEUS, Edwards.

1. PANOPEUS DENTATUS, White. (Tab. XI. Fig. 1.)

Thorace rotundato, lævi, postice coarctato, lateribus productis tuberculis postfrontalibus transversis irregularibus; margine latero-anteriore lobis quinque magnis dentiformibus, lineis elevatiusculis duabus ab angulo latero-anteriore porrectis.

Fronte in lobos quatuor divisa; angulo externo canthi acuto.

Chelis in carpo dentibus duobus conicis, manu externe granulată, interne valde reticulată, ad basin lineâ tuberculată; digito superiore inermi, digito inferiore tuberculis quinque depressis.

Abdomine (maris et feminæ) articulis septem.

HAB. Insulas Philippiuas.

Carapace rounded in front, produced at the latero-anterior angles, and contracted behind, upper surface smooth, marbled with a row of irregular transverse tubercles extending across the postfrontal portion; latero-anterior margin with five large, prominent, dentiform lobes, the anterior three obtuse, the two posterior acute; two curved, slightly elevated lines proceeding inwards from the latero-anterior angle.

Front divided into four lobes, the two inner wide and obtuse, the two outer narrower

and more prominent, upper surface slightly concave, outer angle of orbit acute.

Fore-legs with two strong teeth on the inner and upper part of the fourth joint, the fifth joint slightly granulated externally, coarsely reticulated internally, and with a tubercular ridge at the base; upper claw unarmed, under claw with five round depressed tubercles.

Hind-legs transversely rugosc, fringed with short, stiff setæ.

Abdomen (both of male and female) seven-jointed, the former fringed with long, the latter with short, setæ.

HAB. Philippine Islands.

2. PANOPEUS CAYSTRUS, Adams & White. (Tab. IX. Fig. 2.)

Thorace subtrigonali, antice convexo, marginibus rotundatis lineis impressis obsitis; margine lateroanteriore serratulis tribus subdistantibus.

Fronte, in medio, emarginată, supra sulcată, angulo externo canthi obtuso.

Chelis lævibus, digito superiore arcuato inermi, digito inferiore tuberculis quatuor parvis acutis.

Abdomine (feminæ) articulis scptem.

HAB. Maria Orientalia.

Carapace subtrigonal, rounded in front and at the sides, surface smooth, marked with faintly impressed lines; latero-anterior margin with three rather distant sharp serrations.

Front emarginate in the middle, without lobes, a trifid groove on the upper surface; outer angle of orbit rather obtuse.

Fore-legs smooth, upper claw strong, arched, unarmed; lower elaw with three or four small acute tubercles.

Hind-legs smooth, fringed on the last and penultimate joints with long hairs.

Abdomen (of female) seven-jointed, the second joint narrower than the rest, fringed with short stiff setæ.

Hab. Eastern Seas.

3. PANOPEUS FORMIO, Adams & White. (Tab. IX. Fig. 1.)

Thorace latiore quam longiore, lateribus rotundatis, lineâ valde distinctâ ab angulo latero-anteriore projectâ; margine latero-anteriore lobis quatuor longis rotundatis, dente parvo ad angulum latero-anteriorem.

Fronte lobis quinque subobsolctis, supra sulcatâ, angulo externo canthi fissurâ parvâ.

Chelis manu subtuberculată, digito inferiore tuberculo magno cum multis tuberculis parvis.

Abdomine (maris) articulis septem, articulo tertio ad latera dilatato.

Hab. Maria Orientalia.

Carapace transversely oval, the sides rounded, surface smooth, marked with faintly impressed lines, a strongly marked line extending across the middle from the latero-anterior angle, and a fainter line posteriorly; latero-anterior margin with four long, rounded crenulations, and a small tooth at the latero-anterior angle.

Front with four slightly developed lobes, a bifurcate groove on the upper surface, outer angle of orbit slightly fissured.

Fore-legs smooth, with the upper and outer surface of fifth joint faintly tuberculated, upper claw unarmed, lower claw with one large and several small tubercles.

Hind-legs transversely rugose and slightly granulated, not fringed with hairs.

Abdomen (of male) seven-jointed, the third joint dilated at the sides; fringed with short stiff setæ.

HAB. Eastern Scas.

7. ÆGLE, De Haan.

1. ÆGLE RUGATA (sp.), Milne Edwards. (Tab. VIII. Fig. 5.)

Thorace granulis minutis dense dispositis; margine latero-anteriore lobis quatuor rotundatis distinctis. Chelis sublavibus.

Abdomine (feminæ) articulis septem.

HAB. Insulas Philippinas.

Zozymus rugatus, Edw. Crust. vol. i. p. 385.

Carapace covered with small close-set granulations; latero-anterior margins divided into four rounded very distinct lobes.

Surface of body and fore-legs comparatively smooth.

Abdomen (of female) seven-jointed, and fringed with long, close-set, coarsc setæ.

HAB. Philippine Islands.

8. GALENE, De Haan.

1. GALENE OCHTODES (junior), Herbst. (Tab. X. Fig. 2.)

Cancer thorace lævi, lateribus verrucosis.

Fronte bilobâ, brachiis, carpis, manibus, digitisque verrucosis.

HAB. Maria Orientalia.

Galene ochtodes, Mus. Cat. p. 18. Cancer ochtodes, Herbst. vol. 1. p. 158. t. 8. f. 54.

Carapace smooth, sides verrucose.

Front bilobed, second, third, and fourth joints of chelæ, and the claws, verrucose.

HAB. Indian Ocean.

We have figured a young specimen of this species, which does not seem to be common in collections.

9. PILUMNUS, Leach.

1. PILUMNUS DILATIPES, Adams & White. (Tab. IX. Fig. 4.)

Thorace latiore quam longiore, granulis multis distinctis setigeris obsito; regionibus lincis depressis distinctis separatis; margine latero-anteriore dentibus quatuor, magnis denticulatis.

Fronte emarginată, antice crenulată fasciculis duobus pilosis; margine superiore canthi multidentato.

Chelis externe tuberculis multis rotundatis obsitis, margine superiore setifero.

Pedibus posterioribus valde dilatatis, tuberculis lincisque setigeris instructis.

Abdomine (maris) articulis septem, lævi.

HAB. Maria Orientalia.

Pilumnus dilatipes, White, Pro. Zool. Soc.

Carapace wider than long, eovered with eoarse granulations, each beset with several short setæ; the different regions divided by distinct shallow grooves; latero-anterior margin with four prominent denticulated teeth, the first small, the second wide, and the two posterior equal and triangular.

Front emarginate, with numerous serrations and with two tufts of straight setæ; upper margin of orbit with numerous dentations.

Fore-legs eovered with granules and short stiff hairs on the outer and upper surface, smooth internally.

Hind-legs considerably dilated, beset with fine granulations and numerous rows of short bristles, the edges fringed with long hairs.

Abdomen (of male) seven-jointed and smooth.

HAB. Eastern Seas.

2. PILUMNUS SCABRIUSCULUS, Adams & White. (Tab. 1X. Fig. 5.)

Thorace vix longiore quam latiore, granulis multis parvis setigeris obsito, regionibus lineis depressis vix distinctis separatis; marginibus latero-anterioribus dentibus tribus denticulatis.

Fronte prominente triangulari crenulatà, margine superiore canthi unidentato.

Chelis tuberculis granulosis distinctis obsitis, parte superiore setis brevibus rigidis fimbriatâ.

Pedibus posterioribus scabriusculis, pilosis.

Abdomine (feminæ) lateribus subparallelis, septem articulis.

HAB. Maria Orientalia.

Carapace nearly as long as wide, covered with numerous granulations, each beset with several short setæ; the regions of earapace separated by several faintly impressed grooves, antero-lateral margins with three wide denticulated teeth fringed with stiff hairs.

Front subtriangular, slightly produced, finely erenulated on the margin, which is furnished with a single fringe of stiff setæ; upper edge of orbit with a single rounded dentation.

CRUSTACEA. 45

Fore-legs covered with numerous distinct granular tubercles on the upper and outer surface, and fringed with short hairs.

Hind-legs rough with granules and short hairs, arranged in transverse rows.

Abdomen (of female) villose, seven-jointed, the sides subparallel.

HAB. Eastern Seas.

3. PILUMNUS URSULUS, Adams & White. (Tab. IX. Fig. 6.)

Thorace vix longiore quam latiore, dense tomentoso, granulis multis rotundatis setigeris obsito, marginibus latero-anterioribus dentatis.

Fronte denticulată, fasciculis quinque pilosis longis instructă.

Chelis granulosis, pilis longis dense coopertis.

Abdomine (maris) densc tomentoso, articulis septem.

HAB. Maria Orientalia.

Carapace nearly as long as wide, densely tomentose, covered with numerous large close-set granules beset with very long coarse hairs, latero-anterior margins dentated.

Front toothed, with five tufts of long straight hairs.

Fore-legs covered with coarse granulations, and very long, coarse, slightly curved hairs.

Hind-legs granular, thickly beset with numerous, long, coarse hairs.

Abdomen (of male) densely tomentose, seven-jointed.

Hab. Eastern Seas.

V. PORTUNIDÆ.

The large species of this family are much esteemed as food among the poor islanders of the Meïa-co-shimahs, and in the markets of China large species of Neptunus (N. pelagicus), are frequently offered for sale. Two well-marked genera have been added to this group by our researches in the Eastern Seas, besides numerous species. The island of Balambangan, at the north end of Borneo, harbours the Lupocyclus, which is very active in its habits, keeping close in shore like Lupa, Oceanus, and other swimming crabs; it swims by rapid jerks along the bottom, and, when caught, will wound the fingers by striking side-ways with its spiny fore-legs. The other new genus, Lissocarcinus, was obtained at some considerable distance from land, concealed in the internode of a fragment of floating bamboo, and is a powerful swimmer. The Cancer (Thalamita) admete of Herbst, and the Cancer (Thalamita) prymna of the same Crustaceologist, besides three new species of Amphitrite, and a new species of Neptunus, were likewise procured.

1. LISSOCARCINUS, Adams & White.

Pedipalpi externi articulo tertio, ad basin, latiore quam longiore, ad marginem anteriorem non incisum prope angulum.

Thorax trapezoidalis, postice coarctatus.

Frons prominens, lamellaris, in medio valde incisa. Antennæ internæ articulo secundo elongato, usque ad fissuram porrecto.

Pedes posteriores pedibus Portuno simillimi.

Abdomen (feminæ) articulis septem lateribus subparallelis. Mas adhuc latet.

External pedipalps with the third joint broader at the base than long, and not notched at its anterior margin near the angle.

Carapace trapezoidal, considerably contracted posteriorly.

Front projecting, lamellar, deeply cleft in the middle. Inner antennæ with the second joint elongated and reaching to the commencement of the notch.

Legs very much as in Portunus.

Abdomen (of female) seven-jointed, the sides nearly parallel.

This generic group, described from a female, will be found an interesting connecting link between the genera *Portunus*, *Platyonychus*, and *Polybius*. We have named it *Polybioides* from its resemblance to the genus of Leach, which, as Professor Bell remarks, is of a more decided natatory character than any other Brachyurous form found on the British coast.

1. LISSOCARCINUS POLYBIOIDES, Adams & White. (Tab. XI. Fig. 5.)

Thorace pentagonali, in fronte producto, postice coarctato, lævissimo, multis parvis rotundatis maculis, lineâ distinctâ ab angulo latero-anteriore projectâ; margine latero-anteriore valde dentato, dentibus prorsum inclinatis.

Fronte lamellari, prominente, antice bifidà, antennis lateralibus fronte occultis.

Chelis articulo quinto bicarinato; carina antice valde dentata. Pedibus posterioribus depressis, pari ultimo unguibus valde dilatatis.

HAB. Maria Orientalia.

Carapace five-sided, produced in front, narrowed behind, very smooth on the upper surface, and covered with numerous small round markings, a strong line extending from the latero-anterior angle across the carapace towards the middle line; latero-anterior margin strongly toothed, the teeth directed forwards.

Front lamellar, projecting, bifid anteriorly, covering and concealing the lateral antennæ,

a wide space between the cyes.

Fore-legs with the fourth joint doubly keeled, the keels strongly toothed anteriorly.

Hind-legs flattened, the fifth pair with the penultimate joint more flattened than the corresponding joint of the other pairs, and with a greatly dilated flattened claw.

HAB. Eastern Seas.

2. LUPOCYCLUS, Adams & White.

Pedipalpi externi articulo secundo ad apicem tenuiore (quam in Lupá—L. forceps), articulo tertio minore (quam in Lupá).

CRUSTACEA. 47

Thorax suborbicularis, postice coarctatus, margine latero-anteriore spinis acutis conicis prorsum inclinatis.

Frons semicircularis, in lobos quinque equales divisa; canthi margine superiore subfisso postice, dente magno, conico, curvato.

Chelæ longæ, spiniferæ, pcdcs postcriores graciles, compressæ, pari quinto valde dilatato.

Abdomen (maris) triangulare, articulis quinque; femina adhuc latet.

External pedipalps with the second joint rather more slender towards the tip (than in Lupa forceps), the third joint considerably smaller.

Carapace suborbicular, contracted posteriorly, latero-anterior margin with sharp conical spines directed forwards.

Front divided into five equal dentiform lobes, orbit with the upper margin slightly notched, a large curved conical tooth behind it.

Fore-legs long and spinifcrous.

Hind-legs slender and compressed, the fifth pair greatly dilated.

Abdomen (of male) triangular, five-jointed.

1. LUPOCYCLUS ROTUNDATUS, Adams & White. (Tab. XII. Fig. 4.)

Thorace minutissime punctulato, tuberculis parvis aggregatis lineisque granulosis adsperso, marginibus latero-anterioribus spinis quinque magnis, spinis quinque parvis interpositis; regionibus lateralibus pallidulo-luteo, corneo-fusco discoloratis; in medio thoracis tæniâ latâ rubrâ.

HAB. Balambangan.

Carapace subcircular, slightly narrowed behind, surface irregular, very finely punctulated, and covered with isolated clusters of minute tubercles and transverse granulated lines; the latero-anterior margin with five large, sharp, conical spines directed forwards, and an equal number of small intermediate spines.

Front semicircular, divided into five equal dentiform lobes; orbit with a slight notch at the upper margin, and bounded behind by a strong, curved, conical tooth, directed forwards.

Fore-legs with the third joint furnished with a row of five sharp, curved, conical spincs on the anterior margin, numerous transverse ridges of small tubercles on the upper surface, and a longitudinal granulated line ending externally in a sharp spinc; fourth joint with a strong spine on the upper edge; upper surface of fifth joint with a large spine at the base, and two ridges each ending anteriorly in a prominent spine; claws long, slender, grooved, and slightly curved.

Hind-legs slender, compressed, finely punctulated and granulated, the last pair with all the joints horizontally flattened, the last and penultimate joint greatly dilated and fringed with close-set stiff hairs.

Abdomen (of male) triangular, five-jointed.

HAB. Island of Balambangan, north end of Borneo.

In colour this pretty and curious genus is of a pale yellow, marbled with light pinkish brown on the lateral regions of the earapace, and a broad searlet longitudinal stripe extending from the front to the hind margin, narrowed opposite the orbits and in the middle of the back. The fore-legs are marbled with searlet and yellow, with a broad scarlet band in the middle of the fifth joint, and two broad bands of the same colour on each claw. The hind-legs are light pinkish yellow, with broad transverse scarlet bands.

3. CHARYBDIS, De Haan.

1. CHARYBDIS DURA, Adams & White.

Thorace valde duro, lævi, marginibus lateralibus quinque-dentatis, primo et secundo dentibus ad basin denticulo minuto instructo.

Fronte sex dentibus obtusis, dente externo prominentiore quam in speciebus aliis.

Chelis carpo externe scabro, tuberculato, interne spinâ longâ crassâ in medio, manu margine superiore spinis sex in scrie duplicatâ parallelâ dispositis, externe carinis tribus longitudinalibus.

Pedibus posterioribus externe spinâ magnâ prope extremitatem.

HAB. Mauritium.

Carapace very hard and smooth, lateral margin five-toothed, the first and second teeth with a minute tooth at the base.

Front with six large bluntish teeth, the external tooth rather more prominent than in the other species.

Fore-legs with the fourth joint rough and tubercular on the outside, with a very long thick spine on the middle of the inside, the fifth joint with six spines, in two parallel rows, on the upper edge, and three longitudinal keels on the outside.

Hind-legs with a large spine on the outside near the end.

HAB. Mauritius.

VI. OCYPODIDÆ.

Species of Ocypode and Gelasimus are extremely numerous throughout the islands of the China Sea. Every sandy shore is perforated above high-water mark with the holes of the former, and the banks of the rivers, the mangrove swamps, damp forest margins, and muddy places near the sea, are peopled with the latter, which form oblique burrows frequently penetrating to a considerable depth. The Ocypodes appear to be ehiefly crepuscular in their habits, remaining eoncealed in their holes during the heat of the day, but as evening approaches running side-ways in a curvilinear manner at the edge of the sea, where the waves break along the sandy shores. The Gelasimi remain concealed in their burrows during the high tide or in the dry hot part of the day, but delight to come out of their holes after a shower, or when the tide has receded and left their mud banks moist, but they never

venture very far from their habitations. The clicking noise produced by snapping the claws of their larger fore-leg together, when made by many hundreds at a time, may be heard at some considerable distance. On the least alarm they retreat precipitately to their burrows.

1. GELASIMUS, Latreille.

1. GELASIMUS CULTRIMANUS, Adams & White.

Thorace lævi; marginibus lateralibus rotundatis, sine carinâ acutâ ab angulo canthi externo.

Fronte, inter oculos, lobo parvo rotundato, dilatato; margine canthi inferiore distincte crenulato; chelà majore digitis latis, finibus extrorsum curvatis; digito inferiore in medio profunde sinuato, lobo lato, prope extremitatem margine serrato-crenulato; digito superiore margine inferiore fere recto.

Hab. Insulas Philippinas.

Carapace with the upper surface smooth; the lateral edges rounded, without any sharp keel from the outer orbital angle.

Front, between the eyes, with a small dilated rounded lobe; edge of lower orbit very distinctly erenated; fifth joint of fore-legs with the claws wide, both slightly enrved outwards at the ends; the lower claw with a very wide sinus in the middle, a wide serrato-crenated lobe on the edge near the end; upper claw with the lower edge very nearly straight.

HAB. Philippine Islands.

2. GELASIMUS CRASSIPES, Adams & White.

Thorace valde arcuato, postice subito coarctato.

Fronte lobo sinc pedunculo angusto.

Pedibus posterioribus crassioribus et robustioribus quam in speciebus aliis.

HAB. Insulas Philippinas.

Carapace very much arehed, suddenly narrowed behind.

Front with a lobe, without narrow stalk.

Four hind pairs of legs thicker and stronger than in the other species.

HAB. Philippine Islands.

3. GELASIMUS BELLATOR, Adams & White.

Thorace antice (prope insertionem canthorum pedunculorum) sinuato.

Fronte iu lobum rotundatum subdilatată; chelis manu digitis perlongis; digito superiore lateribus subparallelis, margine prope ad basin tuberculis duobus vel tribus; digito inferiore infra marginato, acie ad basin sinus superficiali tuberculari, dente robusto lato ad extremitatem.

HAB. Insulas Philippinas.

Carapace, in front, just behind the insertion of eye-peduncles, sinuated.

Front slightly dilated into a rounded lobe; fifth joint of the larger fore-leg, with the elaws very long; the upper, or movable claw, with the sides nearly parallel, two or three larger

tubercles on the edge near the base; fixed or lower claw margined on the under side; the cutting cdge with a very wide shallow tubercular sinus at the base; at the end of the sinus, beyond the middle, a strong wide tooth, gradually sloping down to the end, which curves upwards.

HAB. Philippine Islands.

4. GELASIMUS PORCELLANUS, Adams & White.

Oculorum pedunculis perlongis.

Thorace parte frontali non coaretatâ ad basin; parte posteriore longiore quam latera.

Chelis digito inferiore ad fincm incrassato, marginibus internis digitorum amborum tuberculis magnis quatuor inter parvos crenulos.

HAB. Borneonem.

Eye-pedicels very long.

Frontal portion of carapace not narrowed at the base; hind part of carapace much longer than the sides.

Fore-legs with the lower claws thickened at the end, the inner margins of both claws with four larger tubercles amongst the small crenules.

HAB. Borneo.

5. GELASIMUS FORCIPATUS, Adams & White.

Thoraee valde postice coarctato.

Fronte, inter oculos, lobo dilatato, linea acuto-marginata, ab angulo canthi externo porrecta.

Chelá majorc digitis æqualibus, dente prope medium, et prope extremitatem, lobo truncato.

HAB. Borneonem.

Carapace much narrowed behind.

Front with a dilated lobe between the eyes; from the outer orbital angle a sharp-edged line continued beyond the middle of carapace.

Fore-legs with the larger claw nearly equal in size, with a tooth near the middle, and a truncated lobe towards the end; a rather broad impressed line along the middle of each claw; upper edge of palmar portion with a slight ridge; outer side of palm covered with very slight tubercles.

HAB. Borneo.

VII. GONOPLACIDÆ.

The *Macropthalmi* inhabit muddy flats along the sea-shores, and, when disturbed, bury themselves quickly in the yielding soil, leaving the ends, however, of their long telescope-eyes above the surface. When taken, they are quite defenceless, not using their fore-legs as organs of aggression, or erecting and snapping them as do the *Gelasimi*. They are numerously distributed throughout the Philippine Archipelago and the islands in the China Sea.

1. MACROPHTHALMUS, Latreille.

1. MACROPHTHALMUS JAPONICUS, De Haan.

Thorace lato-quadrato, ad latera obtuse dentato; manibus (marium) latere exteriore lævibus et inermibus, interiore glaberrimis, earinâ superiore granulatis; digitis (in maribus) deorsum inflexis.

Japoniee Suna gani, i. e., Cancer arenarius, quod se in arena abscondere solet.

Ocypode (Macrophthalmus) Japonicus, De Haan, F. I. p. 54. t. 15. f. 2. (mas) t. 7. f. 1. (femina.)

Hab. Insulas Mëia-co-shimalis et Japoniam.

Carapace widely-quadrate, sides obtusely toothed; the fifth joint of fore-legs, in the male, smooth and unarmed on the outer side, very smooth on the inner side, granulated on the upper keel; elaws in the male bent downwards.

In Japanese Suna gani, i. e., Sand Crab, because it is in the habit of burying itself in the sand.

HAB. Mëia-eo-shimah Islands; Adams. Japan; De Haan.

2. MACROPHTHALMUS DEFINITUS, White.

Thorace anguste-quadrato, lateribus dentibus tribus, angulo eanthi incluso, dente secundo latiore, dente tertio parvo.

Chelis articulis perlongis vix supra marginatis, digito superiore dente parvo prope basin; digito inferiore sinu valde profundo, manu infra tuberculatâ, interne pilosâ.

HAB. Insulas Philippinas.

Carapace narrowly-quadrate; sides with three teeth, including the orbital angle; the second widest, turned up considerably, the third very small.

Fore-legs with the joints very long, searcely margined above; movable or upper elaw with a very slight tooth near the base; fixed or under elaw with a very deep sinus; fifth joint tuberculated on the under side, hairy on the inside.

HAB. Philippine Islands.

3. MACROPHTHALMUS SERRATUS, White.

Thorace anguste-quadrato, lateribus antiee dentibus tribus robustis, postice carinâ subcrenulatâ.

Chelis, manu ab basin interne dilatatâ, longitudinaliter exeavatâ; digitis pilis longis densis obsitis; digito superiore, in medio, dente truncato.

Pedibus posterioribus, parte superiore, spinâ prope extremitatem.

HAB. Insulas Philippinas.

Carapace narrowly-quadrate, with three strong teeth on the sides in front, succeeded by a slight somewhat erenated keel which margins the rest of the earapace.

Fore-legs with the fifth joint dilated on the inside from the base, and longitudinally hollowed out; inside of both claws densely clothed with long hairs; upper or movable claw with a large truncated tooth in the middle.

Hind-legs with a spine on the upper side near the end.

HAB. Philippine Islands.

2. CHASMAGNATHUS, De Haan.

1. CHASMAGNATHUS CONVEXUS, De Haan.

Thorace gibbo, granulato, brevi-setoso, dorso subtetragono, lateribus areuato.

Fronte areuatâ, medio sinuatâ.

HAB. Maria orientalia.

Octypode (Chasmagnathus) convexa, De Haan, F. 1. p. 56. t. 7. f. 5.

Carapace gibbose, granulated, shortly-setose, subtetragonal on the back, arched at the sides.

Front areuated, sinuated in the middle.

Hab. Eastern Seas.

VIII. GRAPSIDÆ.

The Sesarmæ are found in various localities, sometimes in fresh-water rivulets, among weeds; sometimes under damp logs and stones at a considerable distance from any water, and most frequently among the roots of mangroves in salt-water swamps. They are active and extremely wary in their habits, and, like the Grapsi, very predactious. The Grapsus plicatus is a very common species in Borneo, and appears to vary greatly in colour according to the localities in which it is found. The Grapsi are fond of rocks, over which they run with surprising agility; they frequently remain stationary for hours, basking in the sun, when the tide has just left the high rocks.

1. UTICA, White.

Pedipalpi externi articulo tertio externe recto non dilatato.

Thorace 8-angulato, depresso, post-medium carinâ transversâ valde distinetâ; margine latero-anteriore dentibus tribus; parte latero-posteriore obliquâ, parte posteriore reetâ.

Chelis parvis.

Pedibus posterioribus perlongis, tarso vix dilatato subelongato, pilis fimbriato.

Outer jaw-feet with the third joint, on the outside, straight, not dilated.

Carapace somewhat eight-angled, tabular, a very strong transverse ridge behind the middle; latero-anterior margin with three teeth; latero-posterior part oblique, posteriorly very straight.

Fore-legs small.

Hind-legs very long, tarsus not particularly dilated, somewhat elongated, fringed with hairs as is the preceding joint.

This genus is nearly allied to *Trichopus*, De Haan, which is synonymous with *Varuna*, M. Edwards.

1. UTICA GRACILIPES, White. (Pl. XIII. Fig. 6.)

Fronte latâ, anteriore margine valde recto, post-frontem ad medium thoracem pertinente, cminentiâ magnâ latâ subtriangulari, a transversâ carinâ separatâ per altam lunatam depressionem, lineâ subimpressâ a finibus ad latus carinæ porrectâ. Pedibus gracillimis, pilis fimbriatis.

HAB. Insulas Philippinas.

Utica gracilipes, White, Pro. Zool. Soc., May, 1847.

Front wide, fore-edge very straight; behind it and extending to the middle of the carapace, a considerable, wide, somewhat three-sided elevation, separated from the transverse ridge by a deep lunated depression, from the ends of which a slight impressed line proceeds to the side of the ridge, where it deepens.

Hind-legs very slender, and fringed with hair.

HAB. Philippine Islands.

Mr. Cuming found this species in a fresh-water rivulet among the mountains of the Island of Negros. It was also obtained during the Expedition of the Samarang in the Island of Mindanao, in the deep still muddy fresh-water rivulets near Samboangan, hiding under weeds and rotten wood. When caught, it feigns death, contracting its limbs and rendering them perfectly rigid. Its colour, when alive, is dark-red brown, on the under-surface dark chocolate-brown, lighter on the legs and abdomen, which latter in the female has a yellowish line down the middle.

IX. LEUCOSIDÆ.

Besides several species of Leucosia new to seience, a few Philyra were obtained in the Sooloo Sea, and on the coast of Borneo from a rocky stony bottom; among them was the P. scabriuscula of Leach, which, when alive, is of a chocolate colour, with red-brown legs; the Philyra latifrons (A. & W.), which is of a deep red brown, with orange forelegs; and another with a dead-white polished carapace, marked with dark olive brown, and the fore-legs banded with the same. The Philyræ have much the same habits as the Leucosiæ, being slow-moving, torpid Crustaceans, never using their fore-legs for defence, and living in deep water on a clean rocky or stony floor. A pretty species of Myra was dredged in the Sooloo Sca of a delieate flesh colour, with two blood-red spots on the earapace. The Myra fugax, which is punctulated and dark liver-eoloured on the carapace, and a new species with white carapace and pinkish legs, were also procured; they are found usually in about eight or ten fathoms on a muddy bottom; one species is common in the mud of Manila bay. The Arcaniæ are usually of a dead-white colour, variously marked with red, with the legs spotted or banded; they prefer deep water and a clear gravelly bottom; several were dredged on the coast of Borneo in twenty-four fathoms. The Ixe inhabit very deep water, and are inert and feeble; when taken they contract their legs and remain perfectly immovable. The Iphides are usually found concealed in madrepores and sponges, and live in a eoral bottom in from fifteen to twenty fathoms; they are numerous on the coast of China.

1. LEUCOSIA, Fabricius.

1. LEUCOSIA HŒMATOSTICTA, Adams & White. (Tab. XII. Fig. 2.)

Thorace trapezoidali supra valde convexo, post angulum latero-anteriorem inscissurâ profundâ, maculis multis sanguineis rotundatis obsito.

HAB. Maria Orientalia.

Carapace trapezoidal, very convex, of a light yellow, covered with numerous small round blood-red spots, fewer posteriorly, and in the middle line a dcep notch behind the latero-anterior angle.

Front obtuse.

Fore-legs with round, scattered, blood-red spots, and a large quadrate mark of the same colour on the outer surface of each claw.

Hind-legs with a blood-red band on the upper half of each joint.

HAB. Eastern Seas.

2. OREOPHORUS, Ruppell.

1. OREOPHORUS RETICULATUS, Adams & White. (Tab. VI. Fig. 1.)

Thorace subtrigono, reticulato, fossis subdivisis duabus latero-anterioribus, postice fossâ profundâ, in medio tuberculo clypeoformi, regionibus lateralibus valde elevatis.

Fronte rotundată antice subemarginată supra exsculptă.

Chelis reticulatis.

HAB. Maria Orientalia.

Carapace subtrigonal, covered with a net-work of beaded lines, the intermediate areas finely granulated; a long semilunar, irregularly-shaped cavity extending along the lateroanterior margin on each side, separated by a strong post-frontal septum, each lateral cavity divided in two portions by two over-arching processes, which unite above, leaving a round foramen of communication; the posterior sublongitudinal portion partially divided by a conical projecting process; a small hole in the floor of the hind portion of the latero-anterior fossa; a cavity at the hind part of carapace nearly divided in two by a granulated tongue-shaped tubercle, and bounded posteriorly by two-obtuse tubercles of the hind margin; a solid shield-shaped reticulated process arising out of the hind part of the cavity; a beaded line around the margins of both fossæ; lateral regions convex, elevated into large obtuse prominences; lateral edges coarsely tuberculated.

Front thick and rounded, slightly emarginate, rather deeply excavated on the upper surface.

Fore-legs covered with coarse reticulations, formed of granulated lines. Upper claw spatulate, slightly curved downwards, flattened above, narrow beneath, a row of pits on the outer and inner margins, under edge tuberculiferous; upper surface with several rows of beaded lines. Under claw horizontally inclined, slightly curved upwards, clongately conical;

CRUSTACEA. 55

upper surface sharp and granular; under surface thin and tuberculated; inner surface concave, with two finely granulated parallel lines; outer surface convex, with two rows of holes, and two series of tuberculated lines.

Abdomen (of female) convex, wide, divided into about six pits by strong reticulations formed of granuliferous lines.

HAB. Straits of Sunda.

3. IXA, Leach.

1. IXA MEGASPIS, Adams & White. (Tab. XII. Fig. 1.)

Thorace subgranuloso, canaliculis dorsalibus angustis valde profundis, postice lineâ impressâ profundâ transversâ; lateribus valde productis granulosis retrorsum inclinatis, finibus obtusis, dente terminali parvo curto.

HAB. Borneonem. Insulas Philippinas.

Carapace subgranular, the channelled grooves which separate the middle from the lateral regions very deep and narrow, a deep transverse posterior groove, the lateral prolongations granular, inclined backwards, long and slender, the ends obtuse, and slightly curved forwards, the stiliform tooth at their extremities very short and small.

Hab. Borneo (Tampasook); Philippines (Bohol).

The species, when alive, has the carapace of a light red colour, with dark crimson in the middle, the lateral prolongations of the earapace being purple, with orange tips: the legs are bright red. It differs from the *Ixa cylindrica* in the lateral prolongations being inclined backwards, more slender and longer, the ends more obtuse, and curving forwards, the terminal spine is much shorter and smaller, the surface of the carapace is less granular, the middle region is not so deeply notched on each side, the dorsal grooves are narrower and deeper, and the hind groove is more transverse.

4. HARROVIA, Adams & White.

Thorace subpentagono, dense tomentoso, lineis duabus elevatis, tuberculisque quatuor obtusis; marginibus latero anterioribus dentibus tribus obtusis.

Fronte valde rectà in medio emarginatà, angulo canthi externe prominente dentiformi.

Chelis granulosis, brachio supra spinis duabus interne spinâ duplicatâ, carpo tuberculo unico, manu cylindriceâ sulcatâ, digito ad basin tuberculo parvo externe.

Carapace subpentagonal, densely tomentose, with two transverse raised lines on the upper surface, each ending externally in a prominent blunt tubercle, and two faintly-impressed lines posteriorly; latero-anterior margins with three obtuse teeth, the anterior small and rounded, the middle large and more prominent, and the posterior strong and conical.

Front very straight, emarginate in the middle, the inner angle of the orbits forming a strong tooth in the same line as the front.

Fore-legs granulose, twice the length of the carapace; third joint with two spines on the upper edge, and a double spine on the inner edge; fourth joint with a single tubercle above, and an clongated simple lobe externally; fifth joint subcylindrical, with two longitudinal grooves externally, and a single groove internally.

Claws short; upper elaw curved, with a single small tubercle, externally, near the base, lower edge with numerous teeth; lower claw triangular, grooved externally, the upper edge

sharp and dentate.

Abdomen (of female) seven-jointed, tomentose, the cdges fringed with eoarse short hairs.

1. HARROVIA ALBO-LINEATA, Adams & White. (Tab. XII. Fig. 5.)

Thorace rubro, lineis pallidis.

Chelis carmineis, infra rufescente.

Hab. Borneonem et Insulas Philippinas.

Carapace of a red colour, with light transverse markings.

Fore-legs erimson; under surface of body rufous.

HAB. Borneo. Philippine Islands.

5. IPHIS, Leach.

1. IPHIS NOVEM-SPINOSA, Adams & White. (Tab. XIII. Fig. 1.)

Thorace lævi granuloso, granulis antice aggregatis, postice sparsis, marginibus latero-anterioribus spinis duabus subobtusis prorsum et extrorsum porrectis; marginibus latero-posterioribus spinis duabus retrorsum et extrorsum directis, infra has spinis duabus brevis conicis retrorsum et extrorsum porrectis; margine posteriore, spinâ longâ rectâ in medio retrorsum directâ.

Fronte in lobos duos conicales divergentes divisâ.

HAB. Insulas Philippinas.

Carapace polished, granular, granules close together in front, more sparsely disposed towards the hinder part; latero-anterior borders with two short, stout, somewhat obtuse spines directed forwards and outwards; latero-posterior borders with two long spines directed backwards and a little outwards, with their ends curving upwards, and below these, nearer the middle line, two short conical spines proceeding backwards and outwards; posterior border with a long straight spine in the middle, projecting directly backwards.

Front ending in two conical diverging lobes.

HAB. Philippine Islands (Mindoro).

This species differs from *Iphis septem-spinosa* of Leach, in the general form of the carapace, which is less triangular, more oval, covered with granules, and wants the sharp ridge which extends along the middle of the earapace of *I. septem-spinosa*; in the lateral spines being short and curved; in the possession of two additional spines placed anteriorly to these latter; in the greater comparative size of the upper posterior pair of spines; in the

stouter condition of the prehensile and ambulatory feet; and in the well-marked peculiarity of the front.

6. IPHICULUS, Adams & White.

Thorax sublatior quam longior, denso tomento spongioso obsitus; marginibus latero-anterioribus spinis quatuor fimbriatis; marginibus latero-posterioribus tuberculis duobus obtusis, parte coarctatâ lineis impressis duabus longitudinalibus, et sulco transverso, postice tuberculo subelevatiusculo.

Frons tuberculis duobus depressis, fissà separatis.

Chela, manu gibbosa, digitis perlongis, gracilibus, multis denticulis longis instructis.

Abdomen (maris) ad articulum basalem foveâ profundâ sublongitudinali.

Carapace rather wider than long, covered with a dense woolly tomentum, resembling fine sponge; latero-anterior margins with four fringed spines, increasing in size from the front backwards, the fourth spine, forming the latero-anterior angle, being very strong and prominent; latero-posterior margins with two obtuse tubercles, separated by a sinus; the coarctate portion of carapace marked by two longitudinal and one transverse groove, and ending in a rounded slightly-elevated tubercle.

Front consisting of two very short depressed tubercles, separated by a notch, each tubercle rounded in front; mouth extending beyond the front.

Fore-legs with the fifth joint gibbous; the elaws very long and slender, with numerous fine long sharp teeth.

Abdomen (of male) with its basial joint with a deep sublongitudinal fovea.

1. IPHICULUS SPONGIOSUS, Adams & White.

Thorace fusco, tomento denso spongioso obtecto; lateribus, anteriore spinis quatuor fimbriatis, posteriore tuberculis duobus.

Hab. Insulas Philippinas.

Carapace brown, covered with a thick sponge-like woolly tomentum; sides with four fringed spines anteriorly, and two tubercles posteriorly.

HAB. Philippine Islands.

This genus should properly follow *Ceratocarcinus*, with which it is closely allied, and should be placed in the same group as that Crustacean; it appears, among the *Parthenopidæ*, to hold the same place as *Oreophorus* does among the *Leucosidæ*.

7. TLOS, Adams & White.

Thorax latior quam longior lævis; regionibus lateralibus valde excavatis, marginibus lateralibus trilobatis, margine posteriore excavato, loliâ bicarinatâ; multis tuberculis parvis ad basin circumdatis.

Frons integra rotundata deorsum reflexa.

Chelæ branchio triangulare, carpo supra bicarinato, manu carinâ tuberculiferâ, digitis ad fines curvatis.

Abdomen (feminæ) articulis septem, ovale tuberculosum.

Carapace much wider than long, smooth, the lateral regions cup-shaped, with raised edges, with an anterior and posterior groove; lateral edges divided into three lobes, the front lobe straight and reflexed backwards, the middle simple and rounded, the posterior elevated and wedge-shaped; the middle region with a strong vertical ridge ending behind in an obtuse tubercle, and on each side with two perpendicular three-sided elevations, truncated at their apiecs, with a small tubercle at their fore-bases; posterior margin of carapace excavated, with a large projecting lobe flattened above, with two ridges behind, a rounded elevation in front, and numerous small tubercles near the base.

Front entire, rounded, reflected backwards, showing a central groove on the under surface.

Fore-legs with the third joint triangular, the edges tuberculiferous; the fourth joint with two tubercular ridges on the upper surface; fifth joint with a tubercular keel above; elaws slightly curved at the ends.

Abdomen (of female) oval, tuberculated, seven-jointed, surrounded by an elevated ridge.

It is interesting to see the analogous armature of the carapace with that of *Xanthasia murigera* (White) amongst the *Pinnotheridæ*. The name *Tlos* is from the town of that name in Lycia, so well described by Sir Charles Fellowes in his Asia Minor. It is distinct enough from *Tylos*, another genus of *Crustacca*, so as not to be confounded with it in sound.

1. TLOS MURIGER, Adams & White. (Tab. XIII. Fig. 2.)

Thorace lævi, regionibus lateralibus valde exeavatis; marginibus lateralibus trilobatis; margine posteriore excavato, lobo biearinato multis parvis tuberculis ad basin.

HAB. Borneonem.

Carapace smooth; lateral regions deeply excavated; side-margins with three lobes, hind margin exeavated, a two-ridged lobe with numerous small tubereles at the base.

HAB. Borneo.

X. CORYSTIDÆ.

The genus *Trichocera* is not uncommon among the islands of the Philippine Archipelago, where it is found among the reefs concealed in the coral, or hiding under stones; it has all the habits of the *Xantho* group; the *Corystcs* inhabits rather deep water, preferring the same localities as the *Leucosiae*, which it likewise resembles in its habits; a species of *Gomeza* was dredged by Mr. Cuming in the Philippines, but the other genera of this family do not appear to be found among the islands of the Eastern Seas.

1. TRICHOCERA, De Haan.

1. TRICHOCERA GIBBOSULA, De Haan.

Parva, pilosa, thorace dilatato, brevi, setoso, tuberculato, tuberculis mediis planis quinque transversim dispositis; lateribus 10 dentatis; fronte 5-dentatâ.

HAB. Japonian.

Corystes (Trichocera) gibbosula, De Haan, Faun. Japon. t. 2. f. 4; t. 13. f. 3.

Small, hairy, the carapace dilated, short, setose, tuberculated, the five middle plane tubercles disposed transversely; sides ten-toothed; front five-toothed.

HAB. China Sea. Japan.

2. TRICHOCERA PORCELLANA, Adams & White.

Thorace depresso lævi, lineis multis denticulatis transversis obsito; lateribus spinis quinque robustis acutis curvatis.

Fronte valde supra sulcatà, lobis duobus obtusis dente magno externe.

Chelis lævibus, lineis transversis dentieulatis obsitis; digito superiore supra dentato; digito inferiore tubereulis quatuor supra, lineis duabus longitudinalibus infra.

Pedibus posterioribus lævibus, pilis longis fimbriatis.

HAB. Insulas Philippinas.

Carapace depressed, polished, covered with numerous transverse finely-denticulated lines, some interrupted and some continued into the lateral spines; sides with five sharp strong eurved spines, the first and last simple, the others with small spines at their bases.

Front deeply grooved above, with two obtuse denticulated lobes, each with a large tooth externally.

Fore-legs polished, covered with short finely-denticulated transverse lines; claws long, with the spatulate extremities abruptly curved, upper claw dentated above, with small tubercles below, lower claw with four tubercles above, and two longitudinal denticulated lines externally.

Hind-legs dilated, smooth, fringed with long hairs.

Hab. Philippine Islands.

By Professor De Haan, the most able of modern Crustaceologists, this species would be referred to the division which contains *Xantho*, and we must confess that in its general appearance it has some resemblance to the Chilian genus *Paraxanthus* of Lucas, of which there are specimens in the British Museum; with the genus *Thia* of the family *Corystidæ* it has some considerable analogy, and may be said, in the group *Xantho*, to represent that family. Like the *Cancer (Xantho) integer* of M. De Haan, this species is of a bright yellow brown, with golden hairs (in the dried state), and both species are found in the Philippine Archipelago.

XI. HIPPIDÆ.

The genera which compose this small but very natural group have, so far as I have observed, very nearly the same habits. They swim by sudden rapid jerks, like the *Galathea*, and appear to prefer the deep pools of the coral ledges; they are pre-eminently swimming Crustaeeans, progressing but badly when taken from the water. An interesting addition to

our national collection in the form of Notopus dorsipes, De Haan, was obtained by us in the province of Unsang in Borneo, and a new genus (Cosmonotus) also rewarded our exertions while examining the same locality.

1. COSMONOTUS, Adams & White.

Thorax ovalis, antice acuminatus, lateribus valde compressis, in lineâ mediâ carinâ prominente, lateribus integris, angulo latero-anteriore spinâ brevi acutâ.

Frons profunde incisa, ad latera spina parva acuta.

Chelæ trigonales, interne planæ, externe convexæ.

Abdomen (maris) articulis septem, articulo ultimo trigonali.

Carapace oval, very much compressed laterally, especially in front, with a distinct prominent keel extending down the middle line, very strongly marked in front, but fainter posteriorly.

Front with a very small spine on each side of a deep angular notch, in which are placed

Fore-legs strong, triangular, the upper claw arched, the lower claw small and dentated on the edge.

Abdomen (in the male) seven-jointed.

1. COSMONOTUS GRAYII, Adams & White. (Tab. XIII. Fig. 3.)

Thorace punctis multis depressis obsito.

Fronte valde incisâ externe spinâ parvâ acutâ.

Chelis trigonalibus brachio infra plano, externe convexo lineis multis transversis interruptis, supra carinato pilis fimbriato, interne concavo, carpo incurvato subcompresso, externe convexo, interne spina obtusa; manu compressâ asperâ, margine superiore arcuato; digito inferiore angusto, elongato dente robusto prope extremitatem, digito inferiore brevissimo incurvato; pedibus posterioribus gracilibus brevibus.

HAB. Borneonem.

Carapace about an inch in length and half an inch wide, covered with numerous minute

depressed punctures.

Fore-legs trigonal, the third joint plane on the under surface, the exterior convex with transverse, interrupted, engraved or impressed lines, the upper angle covered with long thick hairs, the inner surface concave; the fourth joint incurved, sub-compressed, convex externally, less convex internally, ending above and in front in a blunt spine; fifth joint compressed, clevated, with the upper edge arched, but not so sharp as in Notopus; the sides convex and covered with asperities or minutely denticulated ridges, interrupted and transverse; upper claw narrow, compressed, elongated, with a sharp apex, and a strong tooth near the distal extremity.

Feet short and weak as in Notopus; the first tibia bicarinated; the tarsus subquadrate, anteriorly bicarinate, with a scalpel-shaped claw; the second tibia one-keeled, with the tarsus CRUSTACEA. 61

oblong, and a sharp elongated trigonal claw; the third tibia subtriangular, the tarsus short, flattened, trigonal, with a falcate claw; the fifth tibia triangular, very short, flattened; tarsus transversely ovate, with a small narrow claw.

Abdomen (of malc) seven-jointed, the joints from the first to the sixth nearly of the same width as in Notopus, the last joint trigonal.

HAB. Bornco (Unsang).

Cosmonotus differs from Notopus, De Haan, in wanting the post-frontal, elevated denticulated ridge; in the dorsal keel ending abruptly in front, instead of terminating in a central frontal spine; in the front being notched, with a single spine on each side; in the carapace being much compressed, more especially in front, and in the produced and angular form, while in Notopus it is almost straight across the front; and in the sides being entire, with a short sharp spine at the antero-lateral angle. The species is named in compliment to J. E. Gray, Esq., F.R.S., Keeper of the Zoological department in the British Museum.

XII. PENÆIDÆ.

A new species of Sicyonia, Edwards, of a scarlet colour, finely variegated with orange and yellow, with a greyish pubescence on the dorsal surface near the crest, was obtained in the Sooloo Sca together with a few Zoææ. The Stenopus, Sicyonia, and Penæus, usually swim in a slow and deliberate manner forwards, and occasionally with a sudden jerk propel themselves backwards. They keep at a considerable distance from the shore and seem to love deep still water, never appearing when the surface of the sca is ruffled.

1. STENOPUS, Latreille.

1. STENOPUS HISPIDUS, Latreille. (Tab. XII. Fig. 6.)

Thorace spinis multis parvis pilisque sparsis obsito.

 $\it Fronte$ acuminatâ gracili sursum directâ, non ultra articulum basali antennarum superiorum pertinente; antennis perlongis filiformibus.

Chelis brevioribus quam paria pedum secunda, longe ultra appendicem lamellarem antennarum inferiorum porrectis. Pari tertio pedum longiore quam totum corpus multis seriebus longitudinalibus dentium acutarum, tarsis duorum parium ultimorum pedum bifidis.

Abdomine lamina media pinnæ caudalis in centro sulcato, supra seriebus duabus spinarum.

HAB. Insulas Philippinas.

Stenopus hispidus, Latr. R. A. vol. iv. p. 93. Cuv. R. N. (Croch), t. 50. f. 2. Edw. Crust. vol. ii. p. 407. t. 25. f. 1. Palæmon hispidus, Oliv. Enc. vol. viii. p. 666. Seba, vol. iii. t. 21. f. 617.

Carapace eovered with numcrous small spines and scattered hairs.

Front pointed, slender, elevated, not extending beyond the basal joint of the upper antennæ; antennæ very long and filiform.

Fore-legs not so long as the second pair, but extending considerably beyond the lamellar appendage of the lower antennæ. Third pair of legs longer than the whole body, with many longitudinal rows of pointed teeth; tarsi of the two last pairs of legs bifid.

Abdomen with the middle lamina of the caudal fin grooved in the centre, and furnished above with two rows of spines.

HAB. Coast of Borneo, and Philippine Islands.

Our figure is coloured from a living specimen taken by me in the China Sea. A. A.

[Additional Species.]

CRYPTOSOMA, Brullé.

CRYPTOSOMA ORIENTIS, Adams & White. (Tab. XIII. Fig. 4.)

Thorace rotundato; marginibus latero-posterioribus rectiusculis. Thorace post frontem et oculos sinc sulcis.

Fronte tribus lobis subacutis.

Pedibus gracilibus; articulo prætarsali tenui, non incrassato.

HAB. Maria Orientalia.

Carapace subcircular, as broad as long, narrowed behind, covered with numerous small red tubereles, and five rows of larger tubereles; latero-anterior margins distinctly dentate; latero-anterior angle with a rather long and sharp spine.

Front with three subacute lobes; upper margin of orbit deeply notched in the middle.

Fore-legs with the third joint armed with two long spines on the outer side near the end, the fourth joint tubercular, the fifth joint compressed, with an elevated toothed crest above, and covered externally with tubercular spines.

Hind-legs smooth, slightly compressed, slender, with the pretarsal joints not thickened or dilated.

Abdomen (in the male) four-jointed.

HAB. Eastern Seas.

This species comes very near to *Cryptosoma cristatum*, figured by Brullé in Webb and Berthelot's Hist. des Iles Canaries (Tab. Crust. fig. 2). The *Mursia cristata*, Leach; *Cycloes granulosa*, De Haan, Faun. Jap. t. 19. f. 3; *Thealia acanthophora*, Lucas, Ann. Soc. Ent. Fr. 1839, p. 579. t. 21. f. 1 (*Mursia armata*, De Haan, Faun. Jap. p. 73. t. 19. f. 2); and this species, belong to a group of *Calappidæ* which seems very widely distributed.

CRUSTACEA. 63

XENOPHTHALMUS White.

XENOPHTHALMUS PINNOTHEROIDES, White. (Tab. XII. Fig. 3.)

Thorace punctulato, sulcis duobus longitudinalibus ab oculis porrectis, lateribus antice ciliatis. Pedibus articulis ciliatis.

HAB. Insulas Philippinas.

Xenophthalmus pinnotheroides, White, Annals and Mag. Nat. Hist.

Carapace with the sides, in front, having a sharp ciliated edge; carapace punctured; two slight waved longitudinal grooves, one extending from each eye over the back of the carapace; most of the joints of the legs ciliated.

HAB. Philippine Islands.

We figure this curious genus on account of our being able to give a coloured representation from a drawing made from life in the Eastern Seas. A. A.

RHABDOSOMA, Adams & White.

Oxycephalus, M. Edwards.

We regret that the state of the only specimen in the British Museum is such that we cannot give the generic character with that detail which we should wish. It is founded on the third species of Professor Milne Edwards, indeed Mr. White has the authority of that eminent Crustaceologist that it is his very species: it is so different from the Oxycephalus piscator, M. Edwards (Crust. III. p. 100. t. 30. f. 10), that we have traced the figure of O. piscator, and added it below that of the O. armatus, to show the difference. Some day it may be proved to be a sexual character, when of course our name will sink, but as yet we know of no such discrepancies in the sexes of these Crustacea.

The head is as long as the rest of the body, and ends in a very long beak; from the state of our specimen we cannot describe this, but indicate it on the plate from a drawing made at the time of capture. The immense length of the body and the beak would sufficiently mark this generic form. The first two pairs of legs are shown in the figure, which must serve till we can procure further specimens, when we hope to give ample details of this very singular crustaceans and to analyse its characters at length. It forms a singularly interesting link between the *Amphipoda* and *Læmodipoda*, uniting, as it were, the two; we should like to have this form examined particularly by Prof. M. Edwards or Dr. Kroyer.

RHABDOSOMA ARMATUM, Adams & White. (Tab. XIII. Fig. 7.)

Oxycephalus armatus, M. Edw. Crust. III. p. 101. pl. 30. f. 10, copied. (Tab. XIII. Fig. 8.)

The specimen described by Professor Milne Edwards was found by MM. Quoy and Gaimard in the ocean between Amboina and Van Dieman's Land, and is now in the Paris Museum. Ours was taken during a calm, floating on the surface of the South Atlantic Ocean.

INDEX.

	Page.		
Micippa philyra	15	Pilumnus ursulus (TAB. IX. Fig. 6.)	Page
—— Thalia	15	Pisa planasia (Tap II Fig. 4 %)	44
Mithrax dichotomus	13	Pisa planasia (TAB. II. Fig. 4, 5)	(
Naxia diacantha		— Sinope	8
Oneinoppe arange	10	Tuandosoma armatum (TAB, XIII, Fig. 7)	68
Oncinopus aranca	3	Schizophrys serratus	16
Neptunus (TAB. II. Fig. 1)	1	spiniger	17
Orcophorus reticulatus (Tab. VI. Fig. 1)	54	Stenopus hispidus (TAB. XII. Fig. 6)	
L'anopeus Caystrus (TAB. IX. Fig. 2)	42	Telmessus serratus (Tap. III.)	61
—— dentatus (TAB. XI. Fig. 1)	41	Telmessus serratus (TAB. III.)	14
formio (TAB. IX. Fig. 1)	42	Tlos muriger (TAB. XIII. Fig. 2)	58
Paramithrax Edwardsii	- 1	Trichocera gibbosula	ib.
Parthenone calappoides (Tan W. Ti. F)	14	Porcenana	59
Parthenope calappoides (TAB. V. Fig. 5)	34	Office graculpes (TAB, XIII, 1850, 6)	53
Tarpeius (TAB. VII. Fig. 2)	35	Xantho cultrimanus	
Pericera cornigera	18	— depressa	39
—— setigera	17	lamellicoro	ib.
tiarata	ib.		40
Pilumnus dilatipes (TAB. IX. Fig. 4)		Xcnophthalmus pinnotheroides (TAB, XII. Fig. 3)	63
	44	Zebrida Adamsii (Tab. VII. Fig. 1)	24
TAD. IA. Fig. 0)	ib.		

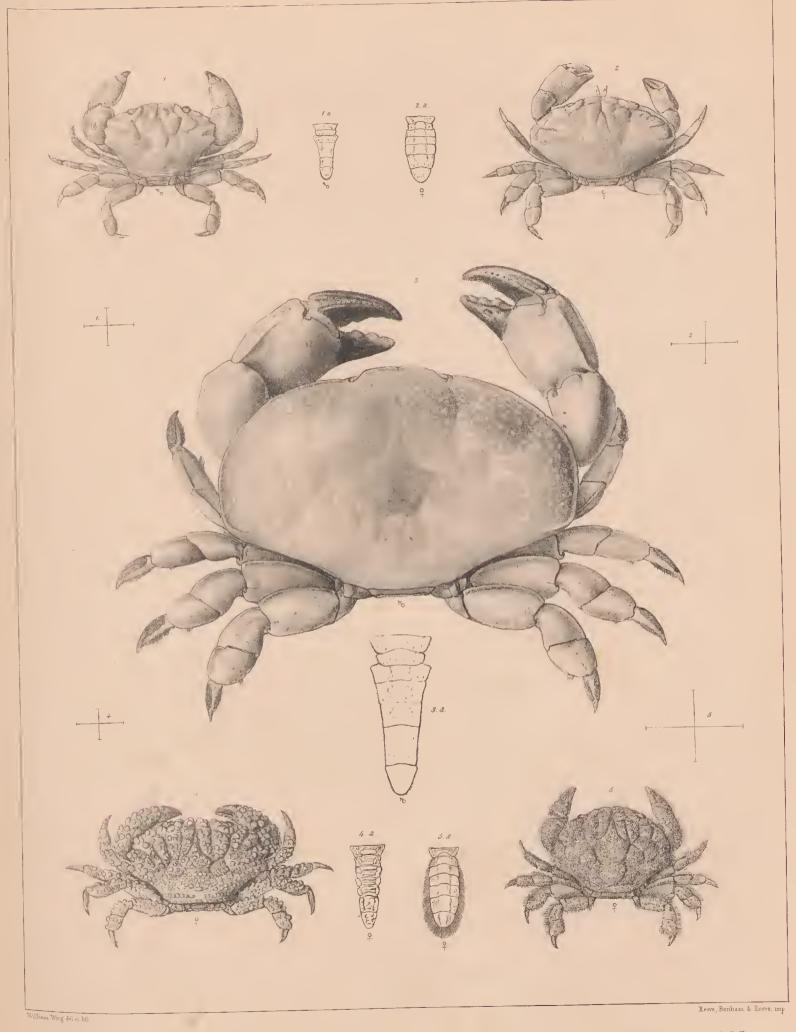

1 ZEBRIDA ADAMSII, White

3 LAMBRUS HOPLONOTUS. Adams & White.

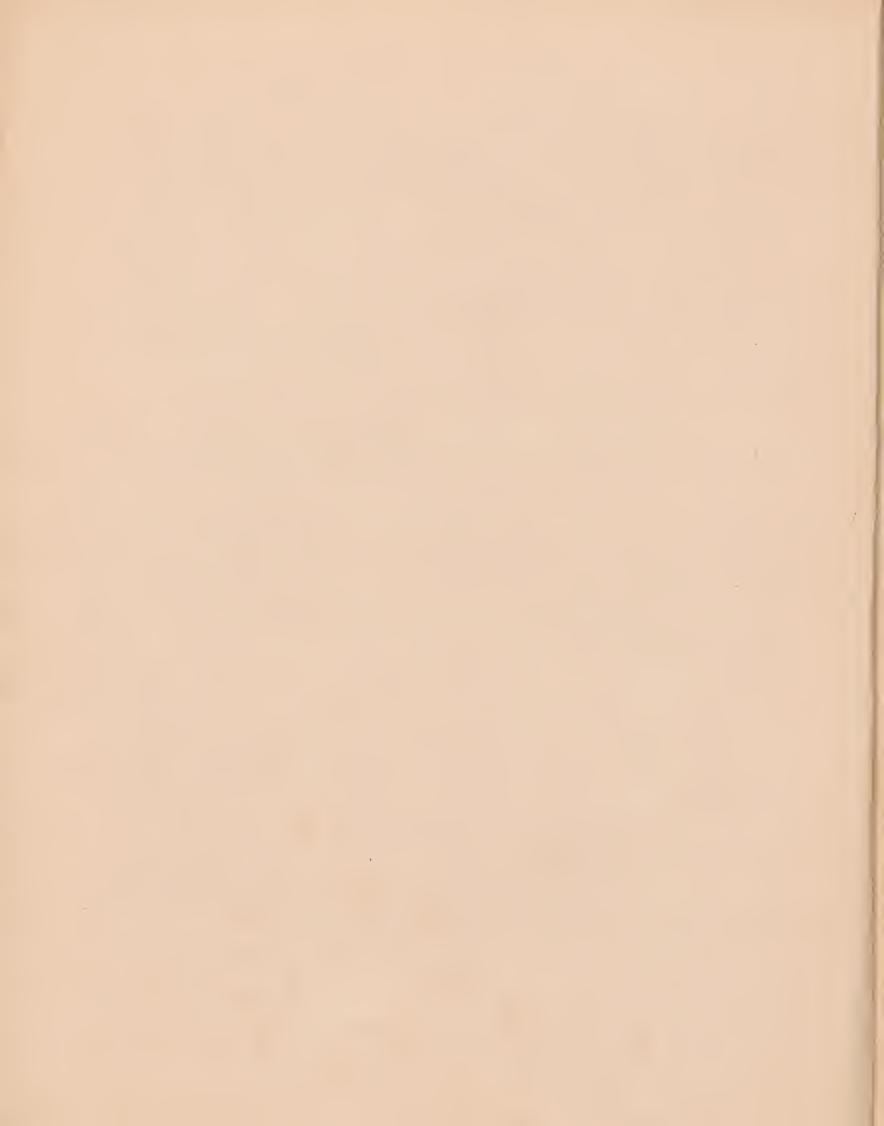

2. PARTHENOPE TARPELUS. Adams & White.

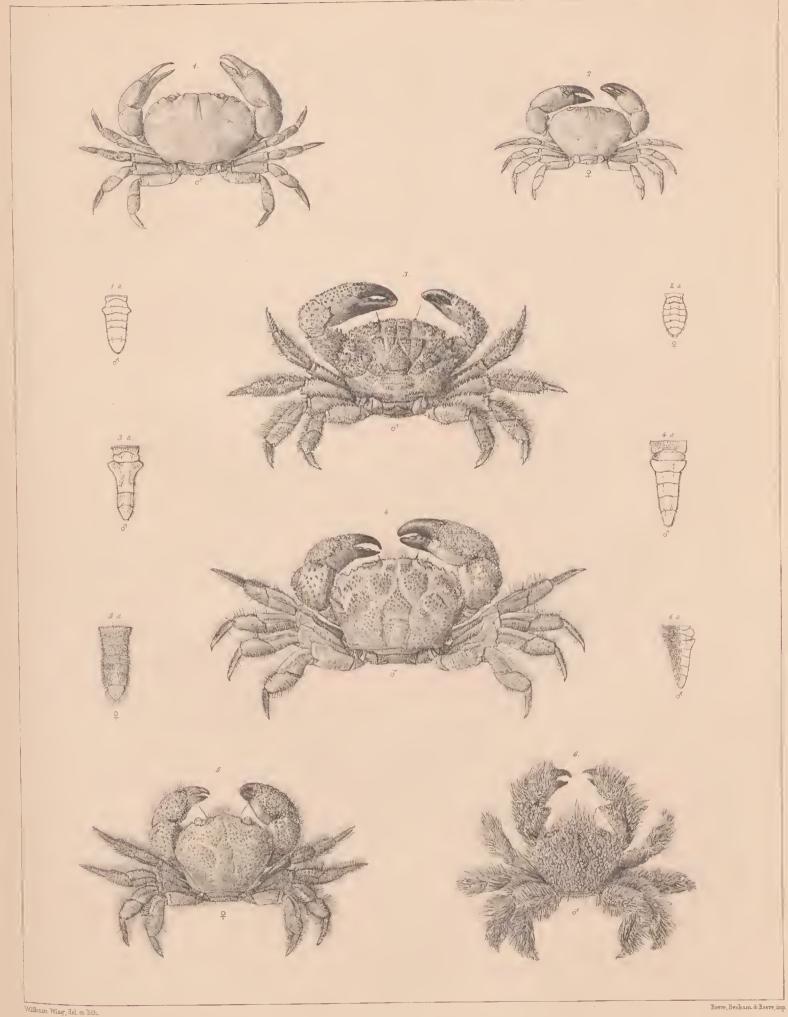

4 CARPILIUS CINCTIMANUS Adams & White

- 1. ATERGATIS LATERALIS Adams & White.
- 2. ATERGATIS INSULARIS, Adams & White.
- 3. ATERGATIS SUBDIVISUS. Adams & White.
- 4. ACTÆA NODULOSA. Adams & White.
- 5 ÆGLE RUGATA Adams & White

1. PANOPEUS FORMIO, Adams & White.

2. PANOPEUS CAYSTRUS. Adams & White.

4. PILUMNUS DILATIPES, Adams & White.

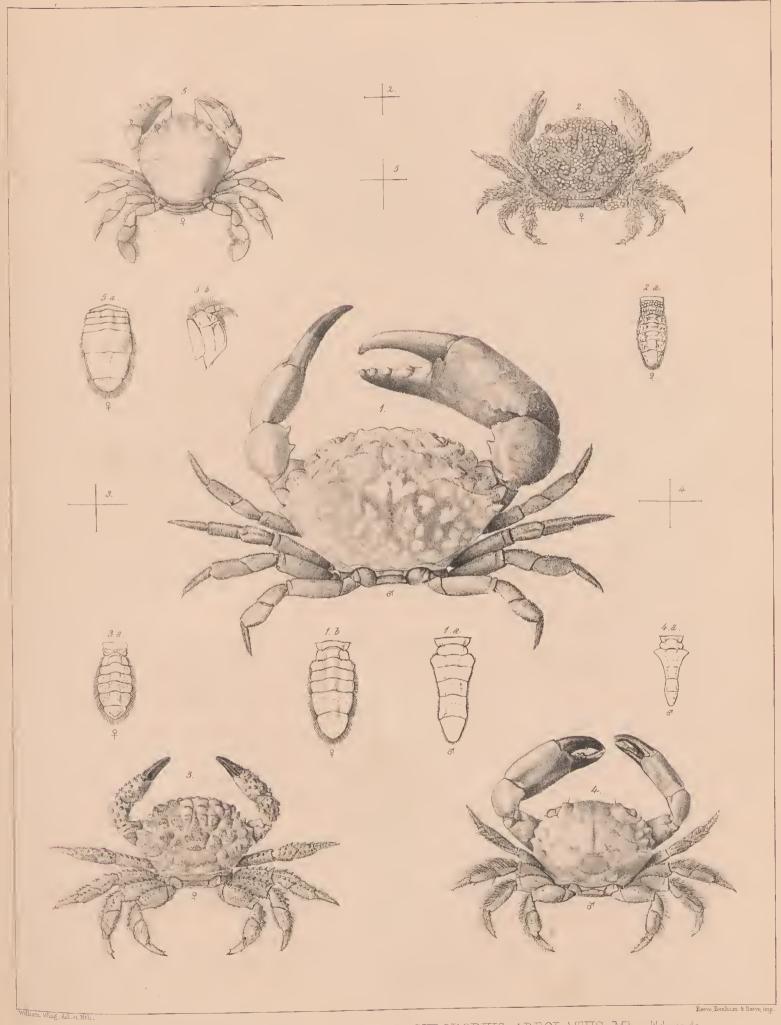

5. PILUMNUS SCABRIUSCULUS, Adams & White.

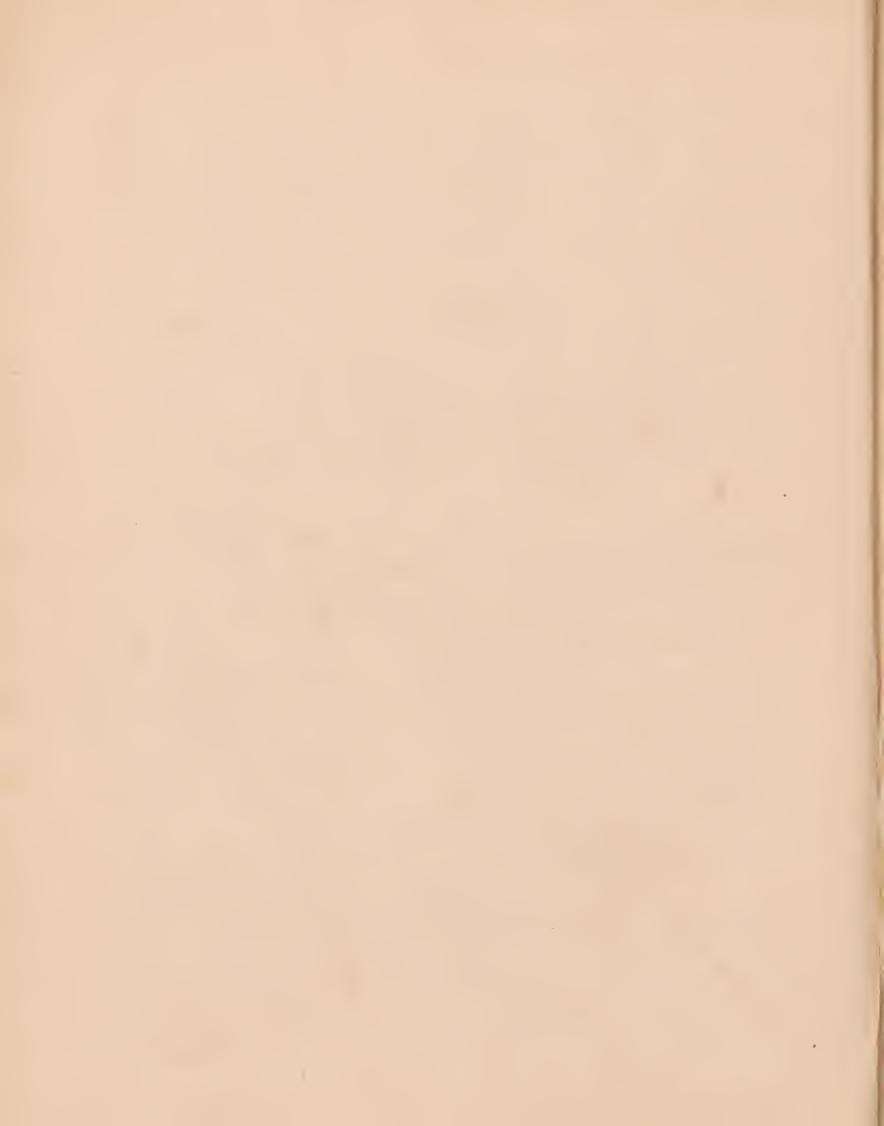

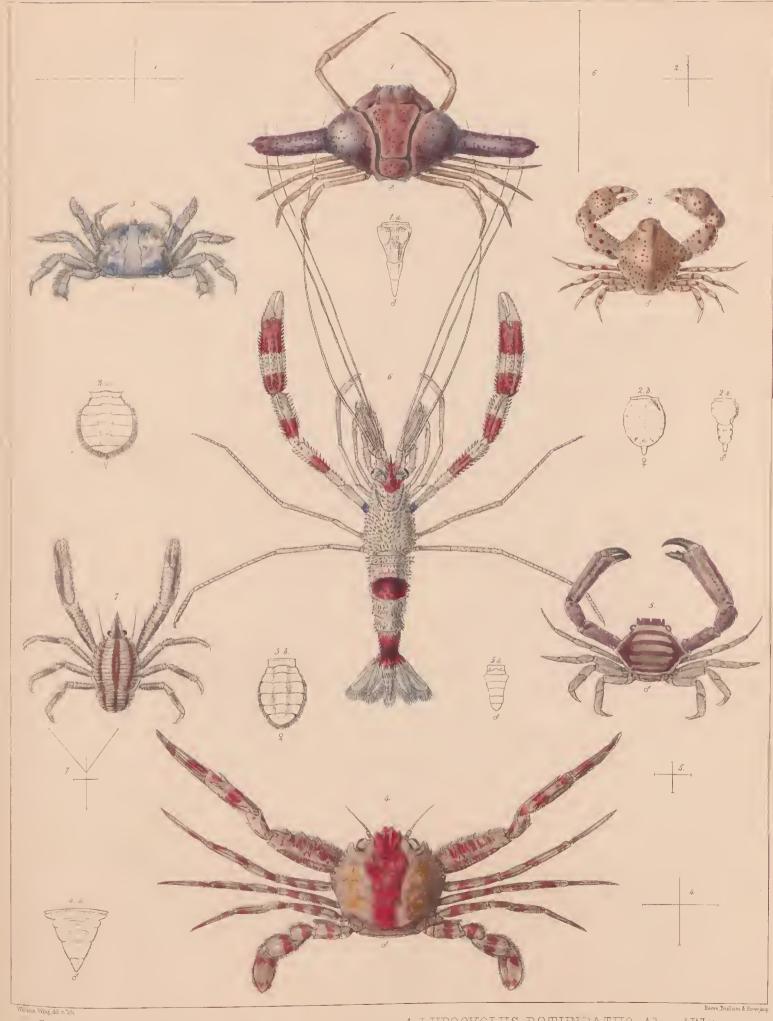

I. CARPILIUS SIGNATUS. Adams &White

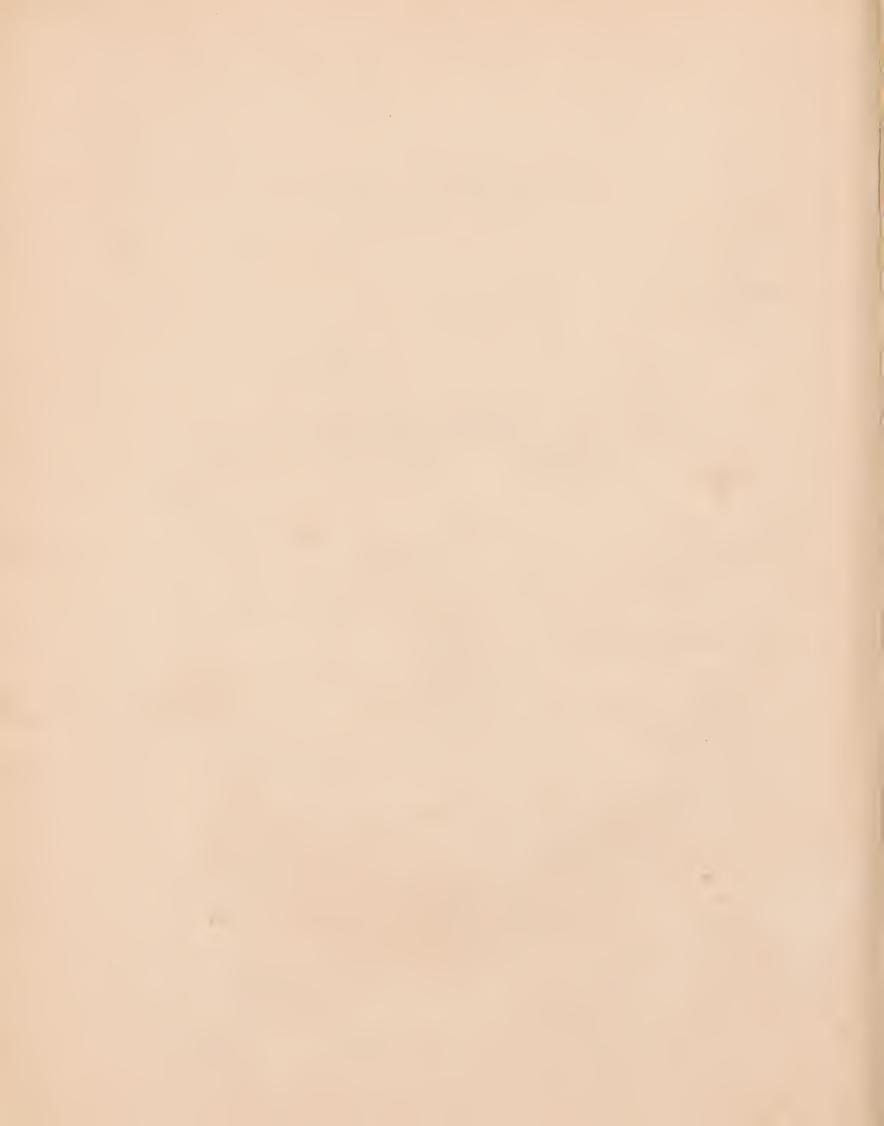

1. PANOPEUS DENTATUS. White.
2. CHLORODIUS AREOLATUS. Milne Edwards
4. CHLORODIUS HIRTIPES. Adams & White.
5 LISSOCARCINUS POLYBIOIDES. Adams & White.

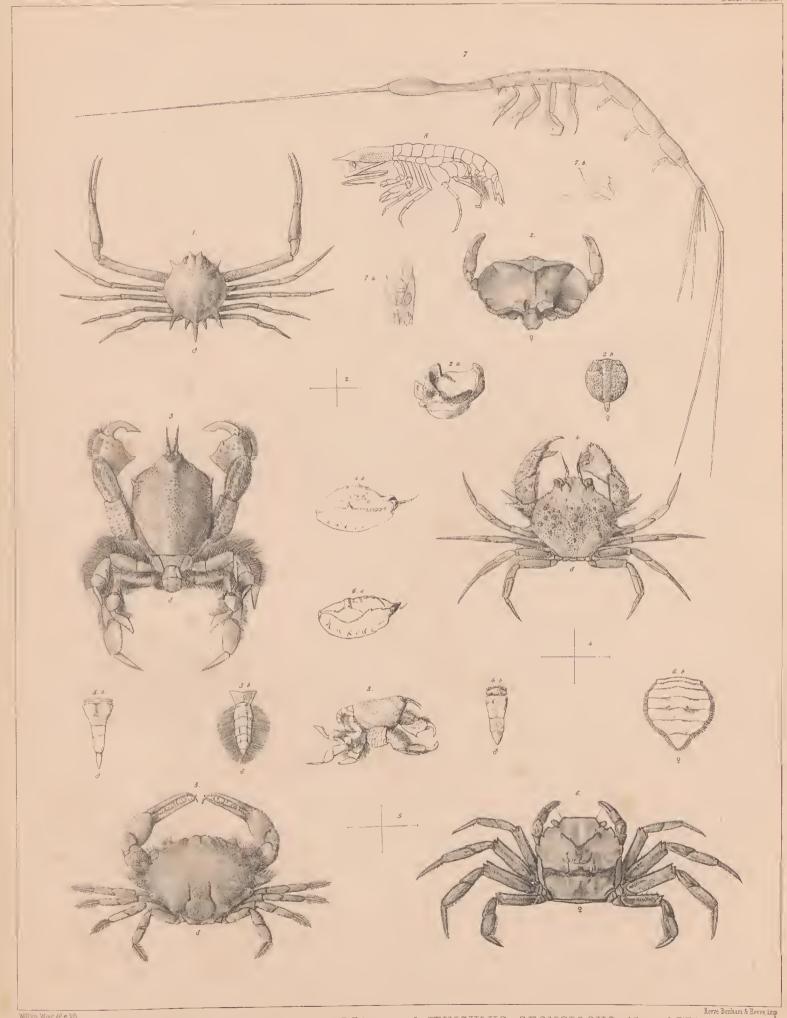

4. LUPOCYCLUS ROTUNDATUS. Adams & White. 5. HARROVIA ALBOLINEATA. Adams & White.

1. IXA 1/ECASPIS. Adams & White 4. LUPOCYCI 2 LEUCOSIA HÆMATOSTICTA. Adams & White 5. HARROVI 3. XENOPHTHALMUS PINNOTHEROIDES. White 6 STENOPU 7. CALATHEA. ELEGANS. White 6 STENOPUS HISPIDUS Latr.

1 IPHIS NOVEM-SPINOSA. Adams & White.

- 2. TLOS MURIGER, White.
- 3. COSMONOTUS GRAYII. Adams & White.
- 4 CRYPTOSOMA ORIENTIS. Adams & White.
- 5. IPHICULUS SPONCIOSUS. Adams & White
- 6. UTICA GRACILIPES White
- 7. RHABDOSOMA ARMATUM (M. Edw.)
- 8. OXYCEPHALUS PISCATOR, Milne Edwards.
